An OASIS WS-Calendar White Paper

Conceptual Overview of WS-Calendar WD01

Understanding inheritance using the semantic elements of web services

By Toby Considine On behalf of the OASIS WS-Calendar Technical Committee

11 WS-Calendar defines calls and semantics to perform temporal alignment in web services

12 interactions. Short running services traditionally have been handled as if they were instantaneous,

13 and have used just-in-time requests for scheduling. Longer running processes, including physical

14 processes, may require significant lead times. When multiple long-running services participate in the

same business process, it may be more important to negotiate a common completion time than a

common start time. WS-Calendar extends the well-known semantics and interactions built around
 iCalendar and applies them to service coordination. This white paper explains some of the issues in

18 generic service coordination as an aid to understanding how and when to use WS-Calendar

19 This white paper was produced and approved by the OASIS WS-Calendar Technical Committee as 20 a Committee Draft. It has not been reviewed and/or approved by the OASIS membership at-large.

68 Why WS-Calendar, why now?

69 As physical resources become scarcer, it is imperative to manage the systems that

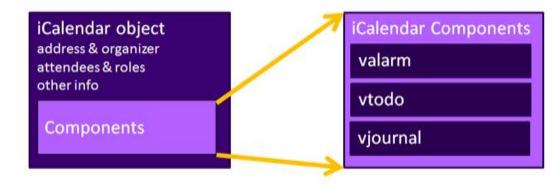

- 70 manage our physical world just as we manage business and personal services. The
- controlling paradigm of our resources shifts from static efficiency to just-in-time provision
- of services. At the same time, technology and policy are moving toward reliance on
- resources that are intermittently available, creating another constantly changing schedule.
- 74 The challenge of the internet of things is to manage the collision of these schedules.
- 75 Service oriented architecture has seen growing use in IT as a paradigm for organizing and
- tilizing distributed capabilities that may be under the control of different ownership
- domains. It is natural to think of one computer agent's requirements being met by a
- computer agent belonging to a different owner. The granularity of needs and capabilities
- vary from fundamental to complex, and any given need may require the combining of
- 80 numerous capabilities while any single capability may address more than one need. SOA
- is seen to provide a powerful framework for matching needs and capabilities and for
- 82 combining capabilities to address those needs. The purpose of using a capability is to
- realize one or more real world effects. When we expose these capabilities for remoteinteraction, we refer to it as a service.
- 85 Physical processes are already being coordinated by web services. Building systems and
- 86 industrial processes are operated using oBIX, BACnet/WS, LON-WS, OPC XML, and a
- 87 number of proprietary specifications including TAC-WS, Gridlogix EnNet, and
- 88 MODBUS.NET. In particular, if building systems coordinate with the schedules of the
- 89 building's occupants, they can reduce energy use while improving performance.
- Service interactions have typically lacked a notion of schedule or of temporal coordination.
 Short running services have been handled as if they were instantaneous, and schedules
- 92 have been managed through just-in-time requests. Longer running processes, including
- 93 physical processes, may require significant lead times. Long-running processes have
- 94 different dynamics than do short ones. For example, it may it may be more important in
- some scenarios to negotiate a common completion time than a common start time.
- 96 Physical services rely on a diverse mix of technologies that may be in place for decades.
- 97 Direct control of diverse technologies requires in-depth knowledge of each technology.
- 98 Approaches that rely on direct control of services by a central system increase integration
- 99 costs and reduce interoperability. Interaction patterns that increase schedule autonomy
- 100 free up such systems for technical innovations by reducing the need for a central agent to
- 101 know and manage multiple lead times.
- 102 An increasing number of efforts are underway that require synchronization of processes
- 103 on an "internet scale". Efforts to build an intelligent power grid (or smart grid) rely on
- 104 coordinating processes in homes, offices, and industry with projected and actual power
- 105 availability; these efforts envision communicating different price schedules at different
- times. Emergency management coordinators wish to inform geographic regions of future
- 107 events, such as a projected tornado touchdown. The open Building Information Exchange
- 108 specification (OBIX) lacks a common schedule communications for interaction with
- 109 enterprise activities. These and other efforts benefit from a common cross-domain, cross
- 110 specification standard for communicating schedule and interval.

111 WS-Calendar builds on iCalendar

- 112 For human interactions and human scheduling, the well-known iCalendar format is used
- to address these problems. Prior to WS-Calendar, there has been no comparable
- standard for web services. As an increasing number of physical processes become
- 115 managed by web services, the lack of a similar standard for scheduling and coordination
- 116 of services becomes critical.
- 117 WS-Calendar is part of a concerted effort to address the issues above. CalConnect,
- 118 working through the IETF, has updated the RFC for iCalendar to support extensibility
- 119 [RFC 5545]. They have submitted a standard for XML serialization of iCalendar which the
- 120 WS-Calendar specification relies on heavily.
- 121 The intent of the WS-Calendar technical committee was to adapt the existing
- specifications for calendaring and apply them to develop a standard for how schedule and
- 123 event information is passed between and within services. The standard adopts the
- semantics and vocabulary of iCalendar for application to the completion of web service
- 125 contracts. WS Calendar builds on work done and ongoing in The Calendaring and
- 126 Scheduling Consortium (CalConnect), which works to increase interoperation between
- 127 calendaring systems.

128 Building on iCalendar's Components

- 129 The iCalendar object includes many elements to support distributed scheduling and
- authorization for events. Transactions are committed based upon distributed decisions
- 131 communicated by systems that are frequently off-line. Calendar management is a rich and
- 132 complex problem whose solutions and techniques are robust and mature. WS-Calendar
- 133 includes service definitions to invoke these behaviors.
- 134 At the heart of the iCalendar message is the components collection. WS-Calendar
- 135 extends the semantics of these components to meet the needs of service integration.

136 137

138

- Figure 1: iCalendar specifies scheduling components that are well known and well understood
- 139 WS-Calendar inherits behaviors and attributes form the iCalendar components to define
- 140 the Interval, the Sequence and the Association. The services scheduling and performance
- 141 alignment are built upon these three components.

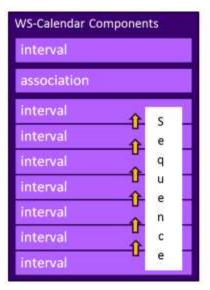

142 Semantic Components of WS-Calendar

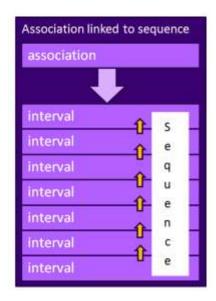

143 WS-Calendar semantics define a structure for common expression of schedules for 144 events or a series of events. Because physical processes may require other supporting 145 services, scheduling of the services described in these structures may be constrained in 146 performance; you can't schedule a reception at a hotel without also scheduling a set-up 147 and a clean-up. WS-Calendar enables the expression of such relationships without 148 requiring the calling party to understand the supporting processes.

149 Other processes may involve parameterized negotiations between services. Intervals may

- 150 be of fixed or variable duration. Purchase prices and quantities may vary over time. The
- 151 intervals may be consecutive, or intermittent. WS-Calendar provides a common
- 152 mechanism for elaborating these details using inheritance and local over-rides to enable
- remote invocation, controlled patterns for service specification, and two-way negotiation
- 154 while achieving parsimonious serialization.

155 The Core Components

156 157

Figure 2: I

Figure 2: Intervals and Associations

The core components of WS-Calendar are the Interval and the Association. Each of theseinherits definitions and structure from the iCalendar components.

160 Intervals

161 The Interval is a length of time associated with service performance. Each interval has a 162 defined payload of XML information. When an interval has a scheduled start time or end 163 time, then we call it a Scheduled Interval.

164 iCalendar components include Relations, whereby the message publisher can specify

- 165 relationships between components. The iCalendar relationships are PARENT, CHILD,
- 166 SIBLING, START, and END. WS-Calendar extends these by adding the temporal
- 167 relationships STARTFINISH, STARTSTART, FINISHSTART, FINISHFINISH, each with an
- 168 offset expressed as a duration. Intervals and relationships together define Sequences.

169 Sequences

- 170 A Sequence is a collection of intervals with defined temporal relationships. The simplest
- 171 sequence is set of consecutive intervals of the same duration. WS-Calendar names such
- a simple, regular Sequence a Partition.

industrial load profile						
energy requirements						
-						
5 megawatts	p					
10 megawatts	a r					
15 megawatts	t					
15 megawatts	1					
15 megawatts	i					
15 megawatts	o n					
3 megawatts						

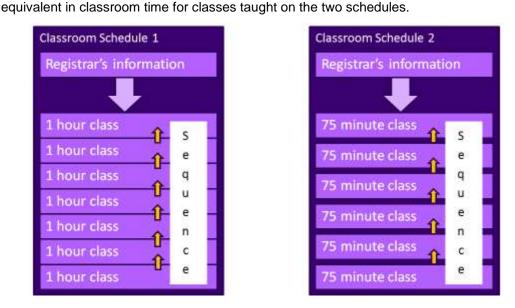

173

174 Figure 3: The Partition, the simplest Sequence

175 Figure 3 depicts a simple repeating time interval along with a single external expression of

- the type of information provided by each interval. In Figure 3, it is labeled Energy
- 177 Requirements; in WS-Calendar, this is an instance of an Association (see below).
- 178 The intervals in a sequence have a coherent set of relationships between them. The
- 179 collection of Intervals in Figure 3 defines a period of time, but not a particular period; there
- 180 is no start or end time for any of the Intervals. If one of them is scheduled, than the
- 181 schedule for each of them can be computed. A particular service interaction can schedule
- the Sequence by defining a Start Date and Time. Another interaction could schedule the
- same Sequence again with a different Start Date and Time.
- 184 Associations
- 185 Associations are all-but intervals used to hold information to define an interval. Any
- 186 information specified in an Interval can also be specified in the Association. So why have187 an Association?
- 188 An Association defines information to be inherited by each Interval in the Sequence.
- Again, referring to the Industrial Load Profile in Figure 3, the Association specifies that
- 190 each Interval is defining Energy Requirements. The amount required varies by each
- 191 interval, but the service of each Interval is the same. Collections of such similar intervals
- are useful in energy and other markets involving volatile resources.
- 193 Repeating intervals are interesting in day-to-day interactions because they are the way
- 194 many services are already delivered. It is useful to be able to vary a Sequence
- 195 parametrically. Take, for example, classroom scheduling at a College. It is typical for
- 196 classes to be scheduled at one hour intervals on Monday, Wednesday, and Friday.

197 Classes schedule on Tuesdays and Thursdays are of 50% longer duration to establish an 198 equivalent in classroom time for classes taught on the two schedules.

199 200

Figure 4: Classroom Schedules

Classroom Schedule 1 shows a schedule for one hour classes. Classroom Schedule 2
 illustrates an every hour and a half schedule for classes, with 15 minute breaks built in.

- 203 The duration of each Interval, and the relationship between each interval and the
- 204 preceding one, can be expressed within each interval. For a regular sequence such as
- those in Figure 4, it is much simpler to express the duration and relationship once, in the
- Association. All Intervals in the Sequence will inherit those elements unless overridden.

207 Summary

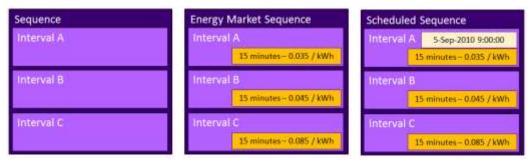

- 208 WS-Calendar uses the Interval, the Sequence, and the Association to define repeating
- 209 instances of service performance. Inheritance within Sequences allows parsimonious
- 210 serialization as well as specific use for a variety of purposes.

211 Assembling Business Objects using WS-Calendar

212 This section provides an overview of how to build regularly recurring temporal service

213 structures using inheritance. It also discusses how to override that inheritance when you

214 need to.

215 216

Figure 5: Building a Sequence into a Business Service

217 In Figure 5, we start with a simple Sequence. To each interval, we can add some contract

or service information. Finally, we can schedule the Sequence by adding a single startdate to the whole Sequence.

220 Inheritance

221 222

225 226 Figure 6: Inheriting Duration from an Association

223 We can reduce the amount of repetition using an Association to create a default duration

for the Sequence. In Figure 6, Sequence 1 and Sequence 2 are identical

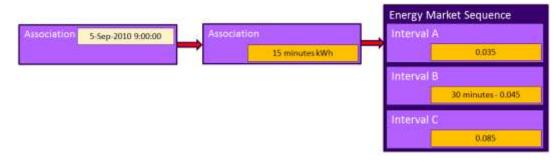

In a similar way, Figure 7 show two identical Sequences, one inheriting a schedule from an association that indicates that Interval A starts at a particular date and time. Note that

- inheritance of a Scheduling option is unique in that it sets the time only on the Interval
- 230 mentioned in the Relationship. This is because all Intervals in a Sequence become
- scheduled when any member of the Sequence is scheduled.

232 Stacking Inheritance

- Associations can also be related recursively, that is, WS-Calendar supports defining an
- Association with another Association, and thereby with the entire sequence.

235 236

Figure 8: Stacked Inheritance introduced

237 In Figure 8, the Sequence is scheduled by adding an association to an existing

Association. That existing Association defined the service offering and the default interval

239 (15 minutes) for the Energy Market Sequence. The existing Association also defined that

Interval A is the entry point for the sequence, i.e., any schedule established will be appliedto Interval A.

242 This type of association enables some interesting service behaviors. A Sequence can be

243 defined as a complete service, with the entry point defined by the Association. This

service could be called a market Offering. Another party can contracts that offering by

referencing the existing intact Sequence as referred to by the Association. In market

service interactions, scheduling a service calling for execution of a contract. Stacked

247 inheritance enables a clean separation of product definition and market call for execution.

248

249

Figure 9: Second Stacking Inheritance example

250 In Figure 9, stacked inheritance is used again in a different way. A catering system

251 defines a standard contract for the HVAC system to support a reception in a hotel.

252 Standard requirements have been created for those activities that are invariant. The

253 elements that vary for each catering job are left indeterminate. The Series is assigned a

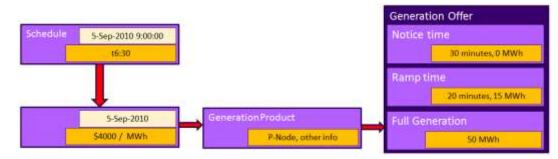

254 name and an entry point using the Association.

The catering software invokes this defined offering at a later time, associating the schedule and the capacity requirements to make a contract. Through inheritance, only the 257 "Event" interval is changed, receiving a capacity (to influence ventilation) and the duration
258 for the reception. Because the exposed Association indicates that the "Event" is the entry

259 point, the reception schedule for 9:00 schedules the series so that the "Event" begins at

9:00. The catering software requires no knowledge of the support services offered in otherintervals.

- 262 Once the contract is created, the room would show up as Busy in calendar inquiries
- 263 during room set-up and break-down.

264 265

Figure 10: Stacking Associations three deep

In the very similar scenario in Figure 10, an energy generation resource has market offering that requires 50 minutes of pre-notification. On September 4th, the generation resource is bid into the next day's market with a price it is willing to accept. The energy production is scheduled and the resource is notified that its bid has been accepted and that its consistent will be required for size and a half have 1

that its services will be required for six and a half hours.¹

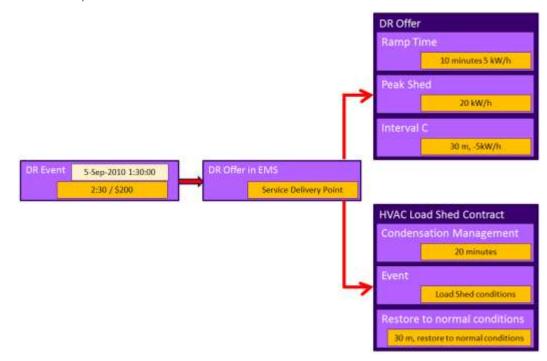

¹ Note: This is meant to be neither a depiction of today's markets, nor a recommendation for tomorrow's. It is merely an illustration of the capabilities and approach.

271 Advanced Scheduling

The examples so far have included only simple partitions and single schedules. This section illustrates some of the flexibility of the WS-Calendar scheduling model

274 Multiple Relationships

- 275 Key interactions in smart energy involve mutually unintelligible systems coordinating their
- behavior for the optimum economic result. Today's interactions are machine to machineinteractions; tomorrows will be business to business.

278 279

Figure 11: One Association, Two Sequences

Figure 11 illustrates an Energy Management System (EMS), which is offering demand

response (DR) to the grid-based markets. The building system integrator has defined the

- 282 Sequence to shut down certain systems, and then to restore them to full operation
- 283 afterwards. This is the HVAC Load Shed Contract.

The energy use effect of these decisions appears in a parallel Sequence, herein the DR Offer. Notice that the lead time in HVAC operation is longer than the lead time in DR; the

- first activities of the HVAC system do not yet reduce energy use. Notice as well, that
- 287 during system restoration, the building will use more energy than it does during normal
- 288 operations, indicated by a -5kWh Demand Response.
- 289 When the DR Event comes from outside, it schedules the event to begin at 1:30 and to
- last for two and a half hours. This offer also comes with a monetary value. When the EMS
- accepts the offer, it shares the DR event as scheduled with the purchaser, and notifies the

Neither the EMS system nor the DR purchaser needs to have any understanding of theunderlying systems. Each needs merely to read the WS-Calendar based service

295 attributes.

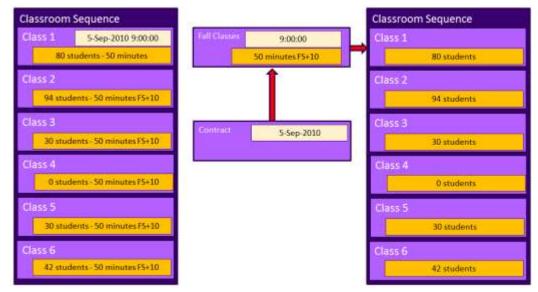

296 Classroom Scheduling Revisited

297 We started this document with an illustration of classroom schedules rendered in WS-

298 Calendar. We now revisit this illustration using the concepts including inheritance and

299 contracts that that paper has illustrated. We started this discussion of Sequences with an

300 illustration of classroom scheduling in Figure 4.

301 302

Figure 12: Classroom Schedules Revisited

In Figure 12, we revisit this using the inheritance. In this high-tech classroom, there are
 systems to warm up, and ventilation levels to be maintained to support each class. The
 registrar's office puts out a schedule for each classroom indicating how many students will
 be in it for each of six periods during the day.

The classes are not really an hour long, but are 50 minutes long with a 10 minute break between classes. A Campus EMS creates a schedule with an Association that includes a 50 minute duration and a FINISHSTART relationship with a duration of 10 minutes. Each day begins at 9:00. This is the standard building system contract for Fall Classes.

To actually schedule contract performance, an association referencing the Fall Classes and the date for each school day during the semester is created.
