**Technical Committee:**

OASIS SOA for Telecom (SOA-Tel) TC

**Chair(s):**

Mike Giordano, [giordano@avaya.com](mailto:giordano@avaya.com), Chair

**Editor(s):**

Enrico Ronco, [enrico.ronco@telecomitalia.it](mailto:enrico.ronco@telecomitalia.it)

**Related work:**

This specification replaces or supersedes:

- Not Applicable

This specification is related to:

- Not Applicable

**Declared XML Namespace(s):**

Not Applicable

**Abstract:**

This document is the first deliverable produced within the OASIS SOA-TEL TC and has the objective of collecting potential technical issues and gaps of SOA standards (specified by OASIS and other SDOs) utilized within the context of Telecoms.

All perceived technical issues on SOA standards contained in this document are structured with a description of the context, a use case, and a rationalization of the possible gap within the standard.

Amongst future deliverables of the SOA-TEL TC there is a Requirements specification, which will aim to extend the current core SOA enabling stack (Web Services and/or REST, etc.) in support of Telecom needs on the basis of the issues identified within the present document.

**Status:**

This document was last revised or approved by the OASIS SOA for Telecom (SOA-Tel) TC on the above date. The level of approval is also listed above. Check the “Latest Version” or “Latest Approved Version” location noted above for possible later revisions of this document.

Technical Committee members should send comments on this specification to the Technical Committee’s email list. Others should send comments to the Technical Committee by using the “Send A Comment” button on the Technical Committee’s web page at <http://www.oasis-open.org/committees/soa-tel/>.

For information on whether any patents have been disclosed that may be essential to implementing this specification, and any offers of patent licensing terms, please refer to the Intellectual Property Rights section of the Technical Committee web page (<http://www.oasis-open.org/committees/soa-tel/ipr.php>).

The non-normative errata page for this specification is located at <http://www.oasis-open.org/committees/soa-tel/>.

## Notices

Copyright © OASIS® 2009. All Rights Reserved.

All capitalized terms in the following text have the meanings assigned to them in the OASIS Intellectual Property Rights Policy (the "OASIS IPR Policy"). The full Policy may be found at the OASIS website.

This document and translations of it may be copied and furnished to others, and derivative works that comment on or otherwise explain it or assist in its implementation may be prepared, copied, published, and distributed, in whole or in part, without restriction of any kind, provided that the above copyright notice and this section are included on all such copies and derivative works. However, this document itself may not be modified in any way, including by removing the copyright notice or references to OASIS, except as needed for the purpose of developing any document or deliverable produced by an OASIS Technical Committee (in which case the rules applicable to copyrights, as set forth in the OASIS IPR Policy, must be followed) or as required to translate it into languages other than English.

The limited permissions granted above are perpetual and will not be revoked by OASIS or its successors or assigns.

This document and the information contained herein is provided on an "AS IS" basis and OASIS DISCLAIMS ALL WARRANTIES, EXPRESS OR IMPLIED, INCLUDING BUT NOT LIMITED TO ANY WARRANTY THAT THE USE OF THE INFORMATION HEREIN WILL NOT INFRINGE ANY OWNERSHIP RIGHTS OR ANY IMPLIED WARRANTIES OF MERCHANTABILITY OR FITNESS FOR A PARTICULAR PURPOSE.

OASIS requests that any OASIS Party or any other party that believes it has patent claims that would necessarily be infringed by implementations of this OASIS Committee Specification or OASIS Standard, to notify OASIS TC Administrator and provide an indication of its willingness to grant patent licenses to such patent claims in a manner consistent with the IPR Mode of the OASIS Technical Committee that produced this specification.

OASIS invites any party to contact the OASIS TC Administrator if it is aware of a claim of ownership of any patent claims that would necessarily be infringed by implementations of this specification by a patent holder that is not willing to provide a license to such patent claims in a manner consistent with the IPR Mode of the OASIS Technical Committee that produced this specification. OASIS may include such claims on its website, but disclaims any obligation to do so.

OASIS takes no position regarding the validity or scope of any intellectual property or other rights that might be claimed to pertain to the implementation or use of the technology described in this document or the extent to which any license under such rights might or might not be available; neither does it represent that it has made any effort to identify any such rights. Information on OASIS' procedures with respect to rights in any document or deliverable produced by an OASIS Technical Committee can be found on the OASIS website. Copies of claims of rights made available for publication and any assurances of licenses to be made available, or the result of an attempt made to obtain a general license or permission for the use of such proprietary rights by implementers or users of this OASIS Committee Specification or OASIS Standard, can be obtained from the OASIS TC Administrator. OASIS makes no representation that any information or list of intellectual property rights will at any time be complete, or that any claims in such list are, in fact, Essential Claims.

The names "OASIS", [insert specific trademarked names and abbreviations here] are trademarks of OASIS, the owner and developer of this specification, and should be used only to refer to the organization and its official outputs. OASIS welcomes reference to, and implementation and use of, specifications, while reserving the right to enforce its marks against misleading uses. Please see <http://www.oasis-open.org/who/trademark.php> for above guidance.

# 1 Introduction

Service-Oriented Architecture, SOA, is a design approach that divides everyday business applications into individual processes and functions, otherwise termed “service components”. These service components can then be deployed and integrated among any supporting applications and run on any computing platform. SOA enables a business to drive its application architecture by aligning the business processes with the information technology infrastructure. In effect the composite application becomes a collection of services communicating over a message bus via standard interfaces and allowing each component to be incorporated into the business process flow creating loosely coupled reusable component architecture.

The use of SOA architectural concepts allows the developer to create complex and dynamically changing applications reaching out to other component providers, who may be inside the organization or an external third party component provider.

From the perspective of an application developer, SOA is a set of programming models and tools for creating, locating, and building services that implement business processes. SOA presents a programming model to build complex composite services, and at this time the current industry approach uses web service technologies to implement SOA.

The next generation of applications are adopting a composite model where the components that are involved in the application execution path may be obtained from the efforts of multiple providers, each specializing in certain core competencies. These components will need to provide an open standards based interface to the application plane that is consumable by the tooling that the business community is comfortable with using. This makes it easier to combine components into applications to meet the needs of customers, suppliers and business partners.

This approach allows the application service provider to offer complex services, whose behavior can be dynamically managed to offer the optimal experience for the end user. As well as providing a mechanism to develop rapid applications there are also various management and deployment areas that need to be handled in this multi-component multi-vendor model as each component may have specific deployment or management considerations.

The use of SOA technology within the telecommunications area is expanding as by using a standardized interface to the network the telecommunications enablers can be exposed for consumption by the IT applications running in the business plane. These interfaces can be based upon various aspects of SOA, WSDL, Web Services Description Language, a REST, REpresentational State Transfer, model or other technology. In any case the consuming application can use the relevant IT tool set to bring these enablers into the business process to supply a real time communications service component.

Part of the work being undertaken by the OASIS SOA-TEL TC is to understand how SOA-related specifications and standards are used within the scope of the telecommunications environment and determine if there are any issues when used in this manner.

The objective of this deliverable is to identify possible technical issues related to the utilization of current SOA standards and specifications in the context of telecommunications. Such issues or gaps are illustrated by means of specific use cases.

Amongst future deliverables of the SOA-TEL TC there is a Requirements specification, which will aim to extend the current core SOA enabling stack (Web Services and/or REST, etc.) in support of Telecom needs on the basis of the issues identified within the present document.

44

## 45 1.1 Terminology

46 The key words "MUST", "MUST NOT", "REQUIRED", "SHALL", "SHALL NOT", "SHOULD", "SHOULD  
47 NOT", "RECOMMENDED", "MAY", and "OPTIONAL" in this document are to be interpreted as described  
48 in [RFC2119].

49

96 **1.3 Non-Normative References**

97

98 **[WS Landscape]** Possible representation of web services specification landscape, available at  
99 <http://www.innoq.com>.

100 **2 Context setting**

101 This section provides a rationale for the classification of the issues presented in the document.  
 102 Literature on SOA is vast, as the theme has acquired increasing importance and relevance over time.  
 103 Contextualizations and generalizations can be a difficult task, since many perspectives could be taken  
 104 into account and importance perceptions may vary depending on reader's interests.  
 105 Nevertheless, Figure 1 is an attempt to provide a context rationalization of items related to SOA: it was  
 106 built not with the intent of being rigorous, but rather to provide a possible classification schema for the  
 107 readers of this document.  
 108

109  
 110  
 111 Figure 1: Reference Schema to classify SOA subject areas  
 112

113 The contributions received and analyzed within SOA-TEL on possible issues of SOA standards in the  
 114 Telecoms context are related to some of the subject areas depicted in Figure 2.

115

116 The list of received contributions is presented hereafter, while in Figure 2 a mapping of the contributions  
117 to the Reference Schema is provided.

- 118 1. **Transaction Endpoints Specification**, related to a possible issue on the W3C WS-Addressing  
119 specification; the necessity to specify the endpoint of a final result of a "process/transaction" (i.e.  
120 asynchronous response) result should be sent.
- 121 2. **Notification**, related to a possible issue on the OASIS WS-Notification specification; the necessity to  
122 specify for the Provider of a notifications service to specify the endpoint to which the Notification  
123 should be sent.
- 124 3. **SOAP Protocol** issue, related on a possible issue on the W3C SOAP specification; the necessity for  
125 an "intermediate SOAP node" to also cover the role of "SOAP ultimate receiver node".
- 126 4. **SAML Token Correlation**, related to a possible issue on the OASIS WS-Security specification; the  
127 necessity of enabling "correlation" of a security token to another.
- 128 5. **SAML Name Identifier Request**, related to a possible issue on the OASIS SAML specification: the  
129 possibility to extend the SAML protocol to enable a Service provider (SP) to register single Users with  
130 an Identity Provider (IdP) "on-the-fly", as the need arises.
- 131 6. **SAML Attribute Management**, related to a possible issue on the OASIS SAML specification: the  
132 possibility to extend the SAML protocol to enable a SP (Service Provider) to transmit user attributes  
133 to be stored within an IdP (Identity Providers).
- 134 7. **User-ID Forwarding**, related to a possible issue in the OASIS WS-Security specification; the  
135 necessity to define a common means to add two (or more) credentials in one message.
- 136 8. **Services exposing Management Interface**, related to possible issues on the OASIS SOA  
137 Reference Model (SOA RM) and SOA Service Component Architecture (SCA) Assembly Model; the  
138 necessity to specify more than one service interface for a single SOA service.
- 139 9. **Metadata in support of Service Lifecycle Management**, related to the possibility to enrich the  
140 OASIS SOA Reference Architecture (SOA RA) with metadata necessary for Service Lifecycle  
141 Management identified within the TM Forum SDF program.
- 142 10. **Universal Communications Profile**, related to the specification of a possible common profile for  
143 universal interoperability across domains.

144

1. Transaction Endpoints Specification
2. Notification
3. SOAP Protocol
4. SAML Token Correlation
5. SAML Name Identifier Request
6. SAML Attribute Management
7. User-ID Forwarding
8. Services exposing Management Interface
9. Metadata in support of Service Lifecycle Management
10. Universal Communications Profile

152  
153  
154  
155  
156  
157

The document is organized in the following sections:

- Section 3, Issues on Addressing and Notification;
- Section 4, Issues on Communication Protocols;
- Section 5, Issues on Security;
- Section 6, Issues on Management;
- Section 7, Issues on SOA collective standards usage.

All perceived technical issues on SOA standards contained in this document are structured with a description of the context, a use case, and a rationalization of the possible gap within the standard.

---

## 158 3 Issues on Addressing and Notification

159

### 160 3.1 Transaction Endpoints Specification

#### 161 3.1.1 Scenario/context

162 The issue presented in this section derives from a concrete case, implemented within an operator's SOA  
163 Middleware.

164 The operator is in the process of deploying a SOA infrastructure, of which some of the constituting  
165 elements are an ESB (Enterprise Service Bus), a BPM (Business Process Manager), some "Service  
166 Consumers (systems or applications), some "Service Providers" (systems or applications).

167 An aspect to be considered is that to satisfy performance criteria it has been decided that the ESB must  
168 be intrinsically "stateless" (i.e. it must not store any persistence information on destination of incoming  
169 service requests).

170 Moreover, the "number" of ESB can vary, i.e. there can be interconnected trunks of different vendors'  
171 ESB.

172

#### 173 3.1.2 Use Case

174 The following Use Case describes the technical problem (Figure 3 and Figure 4). To improve readability  
175 the depicted use case presents only one instance of ESB, but the possible solution to the problem must  
176 satisfy also the cases of multiple instances of ESB.

177 A Service Consumer (C1 or C2) invokes a Service, implemented as a Web Service (Web Service A).

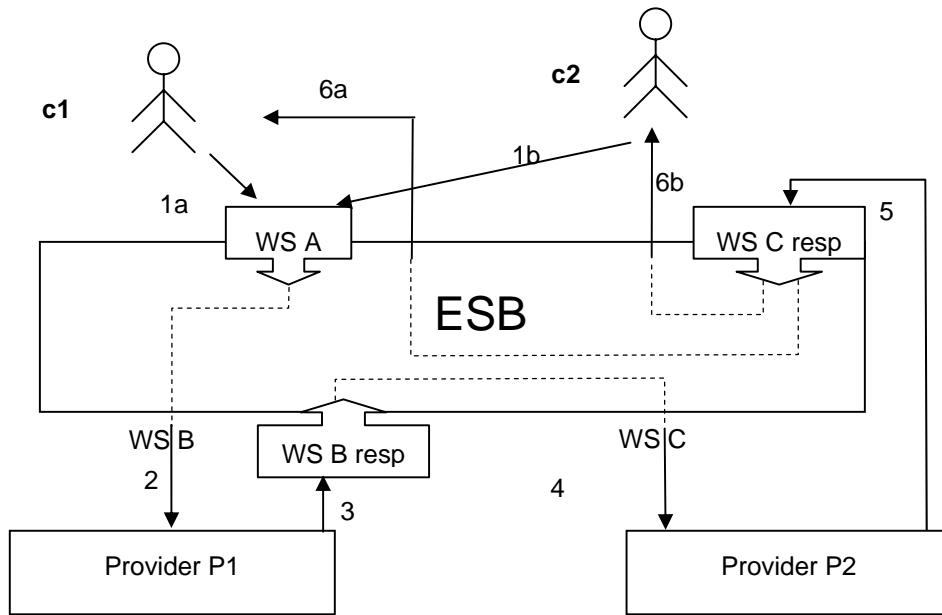

178 Such WSA is achieved as an "itinerary" with the composition of more elementary services, provided by  
179 Provider P1 and Provider P2.

180 The ESB provides intermediary services for final exposition, enrichment and Data reconciliation and  
181 routing.

- 182 • Case **A**: C1 is the originator and final receiver.
- 183 • Case **B**: C2 is the originator and final receiver.

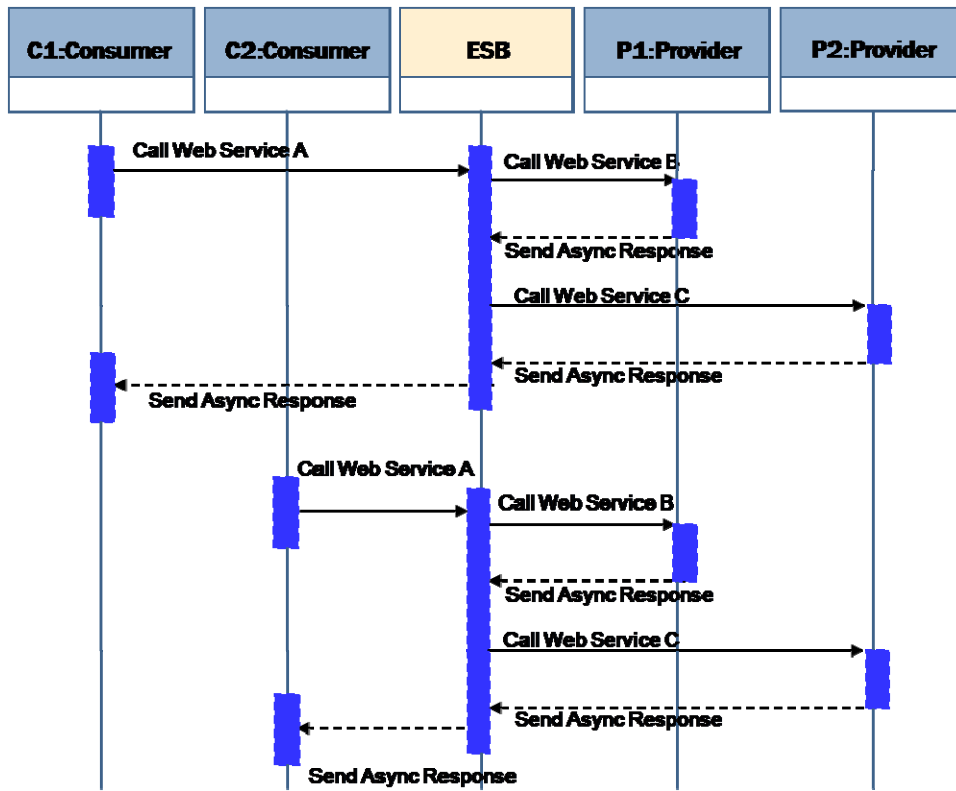

184

185

186  
187  
188

Figure 3: Transaction endpoints scenario

189  
190  
191

Figure 4: Transaction endpoints scenario flow

192 Use Case Steps:

193 **Case A**

- 194 • C1 invokes WSA, exposed by ESB.
- 195 • WSA is executed with the internal composition (transparent to C1) and with intermediary services  
196 provided by the ESB.
- 197 • At the end of the internal interactions, the ESB forwards the response to C1.

198 **Case B**

- 199 • C2 invokes WSA, exposed by ESB.
- 200 • WSA is executed with the internal composition (transparent to C2) and with intermediary services  
201 provided by the ESB.
- 202 • At the end of the internal interactions, the ESB forwards the response to C2.

203

204 **3.1.3 Perceived Technical Issue**

205 With the current knowledge and expertise, in presence of an ESB offering intermediary services, there is  
206 no formal way to specify the endpoint (e.g. C1 or C2) to which the final result of a “process/transaction”  
207 (i.e. asynchronous response) result should be sent.

208 Affected specification is W3C **[WS-A]**.

209

210

211 **3.2 WS-Notification**

212 **3.2.1 Scenario/context**

213 Event-Driven Architectures are extremely important in environments, like Telecoms, where it is necessary  
214 to handle massive network events that have a business value to registered subscribers.

215 Often these solutions rely on proprietary protocols that work against the implementation of SOA  
216 principles.

217 There's a strong technical and business need for a Notify/Subscribe protocol which could be widely  
218 adopted and used by Vendors and Telecom Operators. Moreover the protocol should support the  
219 presence of intermediaries between the Subscriber and the Notifier.

220 In the following, 2 use cases and related issues are presented, one related to a lack of acceptance of an  
221 existing standard by the vendor community, and one on a specific technical issue on existing standards.

222

223 Specifications addressed within this section are:

- 224 • OASIS Web Services Base Notification 1.3 (WS-BaseNotification) **[WS-N]**, OASIS Standard, 1  
225 October 2006, [http://docs.oasis-open.org/wsn/wsn-ws\\_base\\_notification-1.3-spec-os.htm](http://docs.oasis-open.org/wsn/wsn-ws_base_notification-1.3-spec-os.htm)
- 226 • W3C Web Services Addressing 1.0 **[WS-A]** – Core W3C Recommendation 9 May 2006,  
227 <http://www.w3.org/TR/2006/REC-ws-addr-core-20060509>.

228

229 **3.2.2 Use Case (A)**

230 The following Use Case describes a technical problem which is common for a Telecom Operator (ref.  
231 Figure 5).

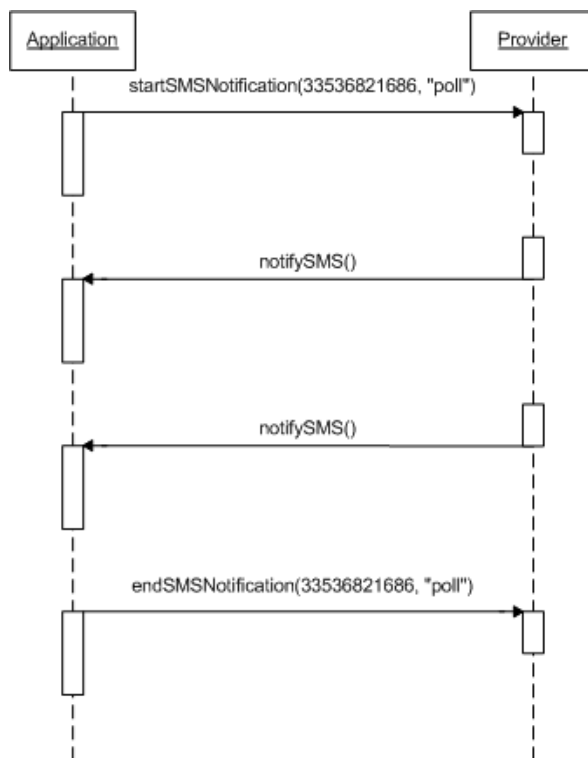

232 An Application wants to be notified when a specific “Large Account Mobile Number” receives an SMS with  
233 a specific keyword in the message content.

234

235  
236  
237  
238  
239  
240  
241  
242  
243  
244  
245  
246

Use Case Steps:

1. The Application informs the Provider that it wants to be notified when the specified Large Account Number "33536821686" receives an SMS containing the word "poll".
2. The Provider notifies the Application when an incoming event from the underlying network responds to the Subscribing criteria.
3. The Application informs the Provider that it does not want to be notified anymore when the specified Large Account Number "33536821686" receives an SMS containing the word "poll".

247  
248  
249  
250

Figure 5: Notification Use Case (a) flow

### 251 3.2.3 Perceived technical issue (A)

252 Currently a commonly used interoperable standard does not exist to address "Notify/Subscribe message  
253 exchanges".

254 The last approved specification, OASIS WS-Notification **[WS-N]**, has been very poorly adopted by the  
255 vendors community and consequently has no interoperability value.

256 The need is that such specification gets endorsed/adopted by the vendor community in order for it to add  
257 value in this specific context.

258

259 Such lack is perceived as a strong market gap with negative impacts for both Telecom Operators and  
260 Third Parties involved in the development of new services:

- 261 1) Operators are limited in their business development since they must rely on costly proprietary  
262 solutions and customizations implemented by vendors;
- 263 2) Third Parties, who are typically involved in developing new services for their customers, can not fully  
264 exploit in their services development the open network infrastructures provided by Telco Operators.

265

266

### 267 **3.2.4 Use Case (B)**

268 The following Use Case describes a second technical problem which is common for Telecom Operators  
269 (ref. Figure 6).

270 An Application must be notified when a specific “Large Account Mobile Number” receives an SMS with a  
271 specific keyword in the message content. There are one or more intermediaries between the Application  
272 and the Provider.

273

#### 274 **Use Case Steps:**

275 1. The Application informs the Intermediary that it wants to be notified when the specified Large  
276 Account Number “33536821686” receives an SMS containing the word “poll”.

277

278 2. The Intermediary sends the subscription request to the Provider.

279

280 3. The Provider notifies the Intermediary when an incoming event from the underlying network  
281 responds to the Subscribing criteria.

282

283 4. The Intermediary sends the notification to the Application.

284

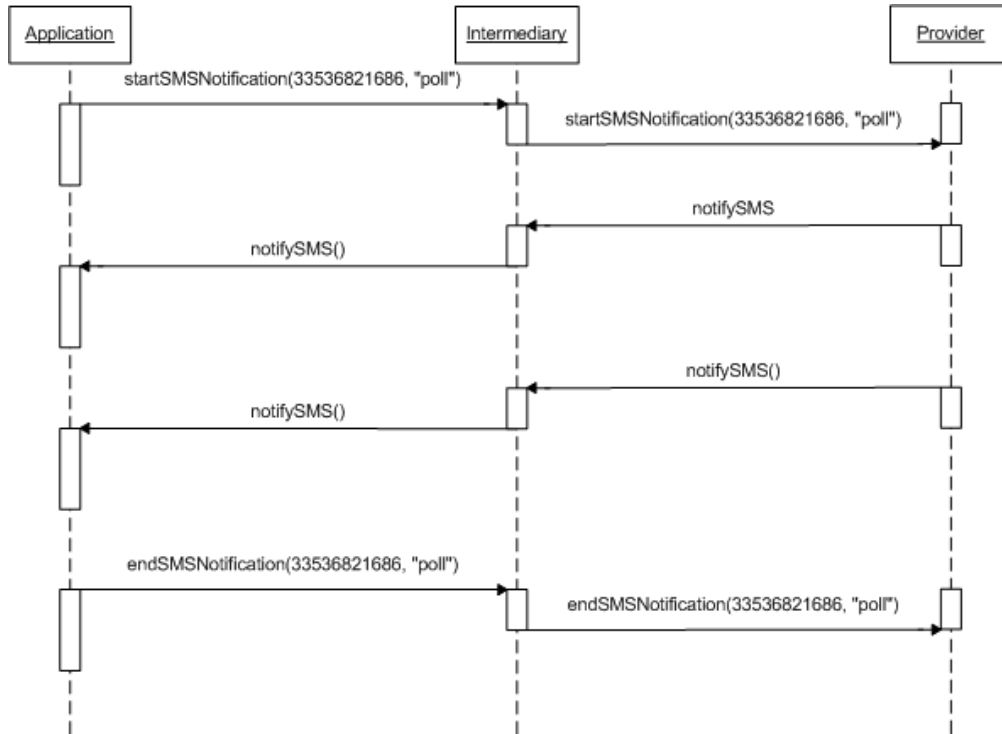

285 5. The Application informs the Intermediary that it does not want to be notified anymore when the  
286 specified Large Account Number “33536821686” receives an SMS containing the word “poll”.

287

288 6. The Intermediary sends the “unsubscribe” request to the Provider.

289

290

291  
292  
293  
294

Figure 6: Notification use case (b) flow

### 295 3.2.5 Perceived Technical issue (B)

296 The last approved specification to support Notify/Subscribe patterns, WS-Notification [WS-N], relies on  
297 W3C WS-Addressing [WS-A] for the asynchronous delivery of notifications, which means that there is no  
298 formal way for the Provider to specify the endpoint to which the Notification should be sent.

299 As an example, in the case illustrated above there is no standard way for the Provider to indicate the  
300 original Application as destination of the notification, due to the presence of intermediary (ies) in the path.

301  
302 The issue on WS-A impacts thus also the WS-N specification. Refer to Section 3.1 within this document  
303 for the technical issues with the WS-A specification.

304 "in presence of intermediary, there is no formal way to specify the endpoint to which the final  
305 result of a "process/transaction" (i.e. asynch. response) result should be sent."

306  
307 The technical problem here exposed prevents Telecom Operators to develop standardized solutions for  
308 the management of "multiple notify/subscribe patterns", and forces to rely on costly customizations and  
309 proprietary solutions.

## 4 Issues on communications protocols

### 4.1 SOAP

#### 4.1.1 Scenario/context

The issue presented in this section derives from a concrete case, occurred within the context of the development of a platform for Mobile Virtual Network Operators (MVNOs).

This section is related to a possible technical issue within the SOAP 1.2 **[SOAP 1.2]** specification, in particular on the “SOAP Intermediary” and “Ultimate SOAP receiver” concepts.

The specification defines the following (within its section 1.5.3):

- **Initial SOAP sender**
  - The SOAP sender that originates a SOAP message at the starting point of a SOAP message path.
- **SOAP intermediary**
  - A SOAP intermediary is both a SOAP receiver and a SOAP sender and is targetable from within a SOAP message. It processes the SOAP header blocks targeted at it and acts to forward a SOAP message towards an ultimate SOAP receiver.
- **Ultimate SOAP receiver**
  - The SOAP receiver that is a final destination of a SOAP message. It is responsible for processing the contents of the SOAP body and any SOAP header blocks targeted at it. In some circumstances, a SOAP message might not reach an ultimate SOAP receiver, for example because of a problem at a SOAP intermediary. An ultimate SOAP receiver cannot also be a SOAP intermediary for the same SOAP message (see [2. SOAP Processing Model](#)).

In particular it is stated that

- A **SOAP Intermediary** processes the header of a SOAP message.
- An **Ultimate SOAP receiver** processes the body of a SOAP message and can not also be a SOAP intermediary for the same SOAP message.

The issue presented in the following Use Case illustrates the need to have a SOAP Intermediary which must process the body of a SOAP message in addition to its “canonical” role of processing the SOAP message header.

The case is included within the activities of deployment of a company-ware SOA infrastructure, of which some of the constituting elements are an ESB (Enterprise Service Bus), some “Service Consumers (systems or applications), some “Service Providers” (systems or applications), a BPM (Business Process Manager), etc.

#### 4.1.2 Use Case

A Service Consumer C1 (e.g. a CRM application) invokes a Web Service to execute a transaction within a specific business process for the management of Mobile Virtual Network Operators (ref. Figure 7).

343 The access point for the Consumer C1 is the ESB, which exposes such Web Service and moreover  
344 executes some of its typical functions such as Data Enrichment and Content Based Routing (CBR).  
345

346  
347

Figure 7: "SOAP" use case representation

349

350 Figure 8 contains the SOAP message which is the request formulated by the Service Consumer (e.g. the  
351 CRM application) to the ESB.

352 The request contains:

- 353 • A SOAP Envelope (in **black** color). This is enclosed for completeness but is not subject of  
354 discussion within this contribution;
- 355 • the SOAP Header, in **red** color;
- 356 • The SOAP message Body, in **blue** (and **green**) color.

357

358 With reference to the SOAP 1.2 specification, the ESB is a "SOAP Node" (ref. Section 1.5 in the [SOAP  
359 1.2] specification).

360

```

<SOAP-ENV:Envelope xmlns:SOAP-ENV="http://schemas.xmlsoap.org/soap/envelope/" xmlns:SOAP-
ENC="http://schemas.xmlsoap.org/soap/encoding/" xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
xmlns:xsd="http://www.w3.org/2001/XMLSchema"
xmlns:m0="http://operator/BSS/MVNO/NetProvisioningCustomTypes">
<SOAP-ENV:Header>
<m:Header xmlns:m="http://operator/BSS/MVNO/NetProvisioningHeaderTypes">
  <m:sourceSystem>String</m:sourceSystem>
  <m:businessID>String</m:businessID>
</m:Header>
</SOAP-ENV:Header>
<SOAP-ENV:Body>
  <m:ActivateLineMessage xmlns:m="http://telecomitalia.it/BSS/MVNO/NetProvisioning">
    <m:Command>
      <m0:description>String</m0:description>
    </m:Command>
    <m:MobilePhoneAccount>
      <m0:telephoneNumber>String</m0:telephoneNumber>
      <m0:ManagedOn>
        <m0:ICCID>String</m0:ICCID>
      </m0:ManagedOn>
    </m:MobilePhoneAccount>
    <m:NetworkProfile>
      <m0:ID>String</m0:ID>
      <m0:TDS>String</m0:TDS>
    </m:NetworkProfile>
    <m:Context>
      <m0:value>String</m0:value>
    </m:Context>
  </m:ActivateLineMessage>
</SOAP-ENV:Body>
</SOAP-ENV:Envelope>

```

361  
362

Figure 8: SOAP message, request formulated by the Service Consumer

363  
364

The ESB for this use case must process the body of the SOAP message in order to perform 2 operations:

366

1. "Data Enrichment",

367  
368  
369

The ESB queries a provisioning system to obtain the IMSI of the asset (mobile phone number) in order to add such data to the message: it invokes a Web Service, exposed by that system, which takes in input the ICCD, present in the message, and returns the IMSI.

370

2. CBR (Content Based Routing)

371  
372

The ESB decides on the final receiver of the SOAP message on the basis of the content of the "Context" field (in **green** in Figure 2).

373  
374

Once such tasks are performed, the ESB deletes the "Context" field from the message and subsequently forwards the SOAP message to the selected Service Provider.

375

**Note:**

376 The Data Enrichment task is executed with the collaboration of other "Service Providers" (different  
377 than SP1 or SP2), but it is not a subject to be discussed within this contribution: for this reason details  
378 are omitted.

379

380 After such tasks are complete, the ESB must forward the SOAP message to the selected Service  
381 Provider, which is the "real" Ultimate SOAP receiver. The message that must be finally sent to the SP by  
382 the ESB is the one depicted in

383 Figure 9.

384 It is fundamental to state that the Service Provider needs the header present in the SOAP message, e.g.  
385 because the content of the "business ID" field can not be associated to the body of the SOAP message.

386

```
<SOAP-ENV:Envelope xmlns:SOAP-ENV="http://schemas.xmlsoap.org/soap/envelope/" xmlns:SOAP-
ENC="http://schemas.xmlsoap.org/soap/encoding/" xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
xmlns:xsd="http://www.w3.org/2001/XMLSchema"
xmlns:m0="http://operator/BSS/MVNO/NetProvisioningCustomTypes">
  <SOAP-ENV:Header>
    <m:Header xmlns:m="http://operator/BSS/MVNO/NetProvisioningHeaderTypes">
      <m:sourceSystem>String</m:sourceSystem>
      <m:businessID>String</m:businessID>
    </m:Header>
  </SOAP-ENV:Header>
  <SOAP-ENV:Body>
    <m:ActivateLineMessage xmlns:m="http://operator/BSS/MVNO/NetProvisioning">
      <m:Command>
        <m0:description>String</m0:description>
      </m:Command>
      <m:MobilePhoneAccount>
        <m0:telephoneNumber>String</m0:telephoneNumber>
        <m0:ManagedOn>
          <m0:ICCID>String</m0:ICCID>
          <m0:IMSI>String</m0:IMSI>
        </m0:ManagedOn>
      </m:MobilePhoneAccount>
      <m:NetworkProfile>
        <m0:ID>String</m0:ID>
        <m0:TDS>String</m0:TDS>
      </m:NetworkProfile>
    </m:ActivateLineMessage>
  </SOAP-ENV:Body>
</SOAP-ENV:Envelope>
```

387

388

389 Figure 9: Message needed by the Service Provider (Ultimate SOAP receiver)

390

391 Nevertheless, given the initial definitions (section 1.5.3 of the SOAP Specification), since the ESB needs  
392 to elaborate the body of the message, it becomes an "Ultimate SOAP receiver" and thus can not be  
393 simultaneously classified as "SOAP Intermediary".

394 The consequence of this is that the ESB can not forward the header of the SOAP message to the  
395 selected Service Provider (i.e. to the "real" Ultimate SOAP receiver).

396 Thus the message really forwarded by the ESB is depicted in

397 Figure 10.

398

399

```
<SOAP-ENV:Envelope xmlns:SOAP-ENV="http://schemas.xmlsoap.org/soap/envelope/" xmlns:SOAP-
ENC="http://schemas.xmlsoap.org/soap/encoding/" xmlns:xsi="http://www.w3.org/2001/XMLSchema-instance"
xmlns:xsd="http://www.w3.org/2001/XMLSchema"
xmlns:m0="http://operator/BSS/MVNO/NetProvisioningCustomTypes">
<SOAP-ENV:Body>
  <m:ActivateLineMessage xmlns:m="http://operator/BSS/MVNO/NetProvisioning">
    <m:Command>
      <m0:description>String</m0:description>
    </m:Command>
    <m:MobilePhoneAccount>
      <m0:telephoneNumber>String</m0:telephoneNumber>
      <m0:ManagedOn>
        <m0:ICCID>String</m0:ICCID>
        <m0:IMSI>String</m0:IMSI>
      </m0:ManagedOn>
    </m:MobilePhoneAccount>
    <m:NetworkProfile>
      <m0:ID>String</m0:ID>
      <m0:TDS>String</m0:TDS>
    </m:NetworkProfile>
  </m:ActivateLineMessage>
</SOAP-ENV:Body>
</SOAP-ENV:Envelope>
```

400

401

402 Figure 10: Message effectively forwarded by the ESB to the appropriate Service Provider

403

404 This is a real case faced by the operator, and to overcome the problem some costly ad-hoc  
405 developments-customizations were necessary to **re-build / reinsert** the necessary header within the  
406 message before the ESB could forward the "complete" message to the final Service Provider.

407

### 408 4.1.3 Perceived Technical issue

409 In the SOAP specification the following is stated.

410 -----

#### 411 2.1 SOAP Nodes

412 A SOAP node can be the initial **SOAP sender**, an **ultimate SOAP receiver**, or a **SOAP intermediary**. A  
 413 SOAP node receiving a SOAP message **MUST** perform processing according to the SOAP processing  
 414 model as described in this section and in the remainder of this specification, etc.  
 415

416 **2.2 SOAP Roles and SOAP Nodes**

417 In processing a SOAP message, a SOAP node is said to act in one or more SOAP roles, each of which is  
 418 identified by a URI known as the SOAP role name. The roles assumed by a node **MUST** be invariant  
 419 during the processing of an individual SOAP message. This specification deals only with the processing  
 420 of individual SOAP messages. No statement is made regarding the possibility that a given SOAP node  
 421 might or might not act in varying roles when processing more than one SOAP message.  
 422

423 **Table 2** defines three role names which have special significance in a SOAP message (see **2.6**  
 424 **Processing SOAP Messages**).  
 425

Table 2: SOAP Roles defined by this specification		
Short-name	Name	Description
Next	"http://www.w3.org/2003/05/soap-envelope/role/next"	Each SOAP intermediary and the ultimate SOAP receiver <b>MUST</b> act in this role.
None	"http://www.w3.org/2003/05/soap-envelope/role/none"	SOAP nodes <b>MUST NOT</b> act in this role.
ultimateReceiver	"http://www.w3.org/2003/05/soap-envelope/role/ultimateReceiver"	The ultimate receiver <b>MUST</b> act in this role.

426  
 427 In addition to the SOAP role names defined in **Table 2**, other role names **MAY** be used as necessary to  
 428 meet the needs of SOAP applications.

429 -----

430  
 431 Due to the fact that the ESB (as a SOAP Node) processes the body of the message, it is classified as  
 432 "ultimateReceiver".  
 433

434 As a consequence, the ESB can not "Forward" the SOAP Header to the appropriate Service Provider (ref.  
 435 Sections 2.7.1 of the SOAP specification) since it has value "ultimateReceiver". The following table  
 436 depicts the behavior of the ESB being an ultimateReceiver.  
 437

Role		Header block	
Short-name	Assumed	Understood & Processed	Forwarded
next	Yes	Yes	No, unless reinserted
		No	No, unless relay ="true"
user-defined	Yes	Yes	No, unless reinserted
		No	No, unless relay ="true"
	No	n/a	Yes
ultimateReceiver	Yes	Yes	n/a
		No	n/a
none	No	n/a	Yes

438

439

440 The case presented shows that a SOAP Intermediary (the ESB), which is clearly not the “ultimate  
441 receiver” of the SOAP message, is forced to assume the role of “ultimateReceiver” since it processes  
442 the body of the message. This prevents the ESB to correctly perform its “proper” intermediary role, since  
443 “An ultimate SOAP receiver cannot also be a SOAP intermediary for the same SOAP message”.

444

445 The perceived technical gap suggested by the operator is that the SOAP specification should be modified  
446 in order to enable a SOAP Intermediary node to “forward” the SOAP Header in automatic mode (thus  
447 without the Header reinsertion) even if such node performs some processing operation over the body of  
448 the SOAP message.

449 Another way of expressing this perceived gap is to state that currently only 3 roles are allowed for a  
450 SOAP Node (i.e. initial SOAP Sender, SOAP intermediary, SOAP ultimate receiver – section 2.1 of the  
451 SOAP 1.2 specification), while a probable fourth role enabling the simultaneous body processing and  
452 header forwarding of a specific SOAP message may be needed.

453

454 Should the specification already enable this, OASIS SOA-TEL TC suggests to modify them in order to  
455 avoid possible ambiguities and misinterpretations.

456

---

## 457 5 Issues on Security

458

### 459 5.1 SAML Token Correlation

#### 460 5.1.1 Scenario/context

461 The issue presented in this section derives from a concrete case of telecommunications services' sales  
462 and post-sales: in particular the activation and provisioning of ADSL service to residential customers.

463 The business process under analysis is complex and necessitates to be orchestrated by a BPM  
464 (Business Process Management) application.

465 Such process is a "long-running" type process: in fact one of its tasks requires a human intervention  
466 within the central office, which can be executed within hours (or days).

467

468 This implies that the process must be handled in a different mode from the "security management"  
469 perspective.

470

471 This section addresses potential issues within the OASIS Web Services Security specification, **[WS-S**  
472 **1.1]**.

473

#### 474 5.1.2 Use Case

475 A consumer, e.g. a CRM application invokes a service to execute a specific business process, the  
476 activation of ADSL services for a residential customer.

477

478 The BPM application gets in charge of the orchestration/execution of such processes.

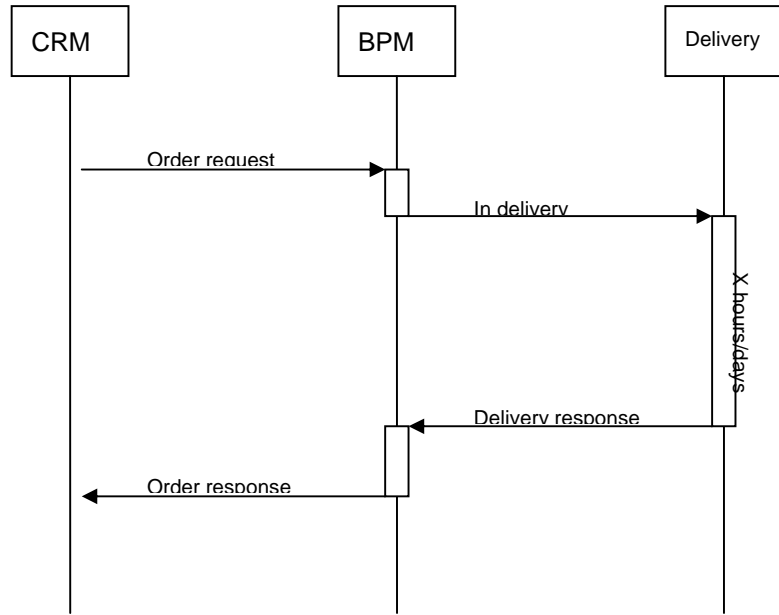

479

480 Given the fact that the process is "long-running", the BPM shall, at a given point, suspend the  
481 orchestration/execution of the process until it will receive a specific "activity closure" event from a back  
482 office system once the appropriate technician will have terminated his manual tasks.

483

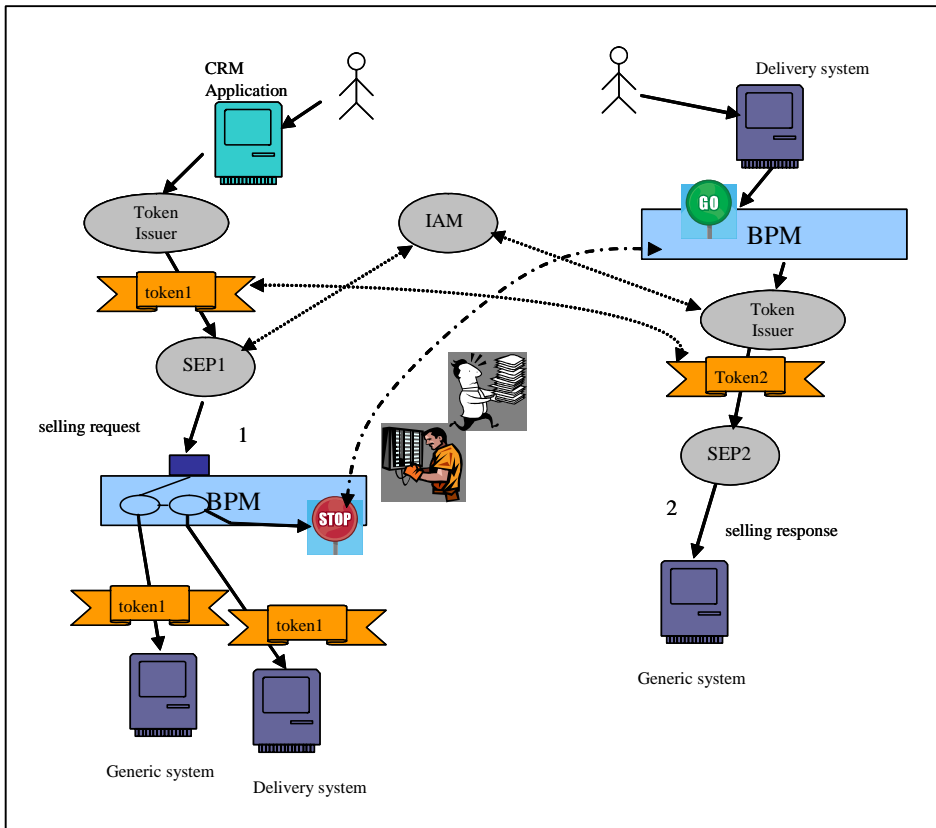

484 The following schema Figure 11 depicts a simplified transaction diagram, while Figure 12 provides a  
485 pictorial representation of the Use Case.

486

487  
488  
489  
490

Figure 11: Simplified transaction diagram for the "SAML token correlation" use case

491  
492  
493  
494

Figure 12: "SAML token correlation" use case: pictorial representation

495 **Use Case steps.**

- 496 • The CRM sends an ADSL activation request.
  - 497 • The consumer (CRM) provides its credentials to a Token Issuer and requires the generation of a  
498 security token, “*token1*”. The token is associated to the initial message and has limited duration, since  
499 extending it would mean to have a weaker security policy.
  - 500 • The Security Enforcement Point, interacting with the policy decision point (IAM) (Identity Access  
501 Manager), applies the authentication and authorization policies.
  - 502 • The BPM orchestrates the process interacting with the various services exposed by the involved  
503 systems within the company SOA infrastructure. All interactions are executed with the “*token1*” as  
504 security token.
  - 505 • When appropriate, the BPM invokes a service exposed by a Delivery system to obtain a physical  
506 configuration within the central office. At this stage the BPM suspends the execution of the business  
507 process (the duration of the task may require hours or days), awaiting for the reception of a specific  
508 “activity closure” event.
  - 509 • The Delivery System activates the technical configuration task.
  - 510 • A human intervention is performed within the central office.
  - 511 • Once this task is terminated, the technician reports the “activity closure” on the Delivery system,  
512 which generates the “activity closure” event for the BPM.
  - 513 • The BPM resumes the suspended process, invoking the “next step” in the ADSL activation process.
  - 514 • If the security token “*token1*” is expired, the BPM requests the Token Issuer to generate a new  
515 security token, “*token2*”, since the previous is not valid any more.
  - 516 • The remaining portion of the process is executed utilizing the new security token, “*token2*”.
- 517

518 **5.1.3 Perceived Technical issue**

519 In the described scenario the issue is related to which credentials (capabilities) must be utilized to  
520 generate the security token “*token2*”.

521 The BPM is responsible for the orchestration/execution of the process, and is the entity which is entitled  
522 to request the generation of the new security token “*token2*”, which is of course different from “*token1*”.

523 This is a weakening factor for the “security architecture”, since an element of the middleware  
524 infrastructure (the BPM) would need to request the generation of security tokens which are not  
525 “correlated” (or “directly coupled”) to the real entity which requires the initiation of the business process  
526 (i.e. the CRM application, thus the CRM sales representative) and to the business process itself. It is a  
527 requirement for the Telecom Operator to reduce such potential security threats.

528

529 It should be possible for the BPM to request the Token Issuer to generate a new token “associated” to the  
530 “*token1*”, and to maintain evidence of that correlation, in order to authorize the BPM itself, once security  
531 checks are validated by the IAM, to invoke all pending services within the second part of the process  
532 because such invocations are “really” part of a “security authorized” business process.

533

534 The WS-Sec specification [WS-S 1.1], in Section 7 - row 824, states that mechanisms for referencing  
535 security tokens are defined.

536 In row 870 the following is stated:

537 -----

538           870 /wsse:SecurityTokenReference/@wsse:Usage

539           871 This optional attribute is used to type the usage of the

540           872 <wsse:SecurityTokenReference>. Usages are specified using URIs and multiple

541           873 usages MAY be specified using XML list semantics. **No usages are defined by this**

542           874 **specification.**

543 -----

544

545 Thus, from a syntactical perspective, the specification enables the “correlation” of a security token to  
546 another one, but it does not prescribe how such correlation should be formalized.

547

548 Moreover, within non-normative Appendix D “SecurityTokenReference Model”, specific examples of  
549 security token referencing are provided, with emphasis of the “signature referencing”.

550 Within this appendix, Row 2413 to 2432 do provide an example of “non-signature references”, but the  
551 specification states that

552

553 *2430 This may be an expensive task and in the*  
554 *2431 general case impossible as there is no way to know the "schema location" for a specific*  
555 *2432 namespace URI.*

556

557 In conclusion, the lack of normative guidelines on how to address this problem is perceived as a strong  
558 issue for a Telecom Operator because the “correlation” problem must anyhow be solved, but adopted  
559 solutions result to inevitably be proprietary, costly, non-standard, vendor/platform dependent  
560 customizations.

561

## 562 **5.2 SAML Name Identifier Request**

### 563 **5.2.1 Scenario/context**

564 The context of this section is that of a SP (Service Provider) being newly added to the circle of trust of an  
565 IdP (identity Provider).

566

567 Currently, as soon as a SP becomes a member of the circle of trust of an IdP, the SP is forced to import  
568 all of the SP’s Users into the IdP’s databases.

569 The objective of this contribution is to propose a modification to the current SAML V2.0 specification  
570 (saml-core-2.0-os.pdf) so that the SP can be enabled to register single Users with the IdP “on-the-fly”, as  
571 the need arises. Such goal can be achieved with the introduction of a new SAML protocol, named “SAML  
572 Name Identifier Request” within the SAML specification.

573

574 SAML supports SPs to get attributes about Users from an IdP. Regarding name identifiers, the SP usually  
575 sends an AuthnRequest to the IdP. Then, the IdP sends an AuthnResponse containing a NameIdentifier  
576 (“Subject”) back to the SP. However, if a SP is newly added to the circle of trust of an IdP, the IdP will not  
577 know of the User identifiers of the SP, which is required in order for the IdP to authenticate the Users of a  
578 SP.

579

580 The issue highlighted in this section aims at possibly extending the SAML specifications.

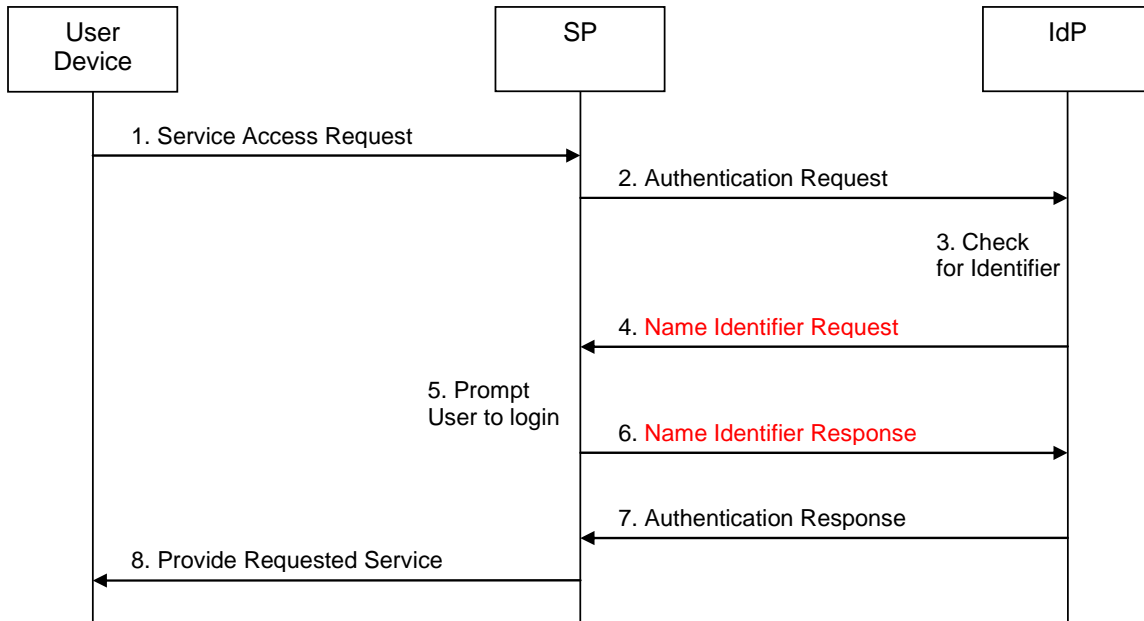

581

### 582 **5.2.2 Use Case**

583 A user device, a SP and an IdP are the actors of this use case of the SAML Name Identifier Request  
584 mechanism. The SP is new to the circle of trust of the IdP. The IdP does not know a name identifier of the  
585 user device. The IdP requests a name identifier from the SP, who sends the desired name identifier to the  
586 IdP.

587

588 Figure 13 provides a high-level message flow illustrating this SAML Name Identifier Request use case.  
 589 Messages 4 and 6 belong to the SAML Name Identifier Request protocol this contribution is aiming at.  
 590 These messages are interlaced into the SAML Authentication Request and Response exchange between  
 591 SP and IdP and are not specified in SAML V2.0 yet (therefore, marked in red):  
 592

593  
594

595 Figure 13: "SAML name Identifier request" use case: pictorial representation

596

597 The single steps of this use case are as follows:

598

- 599 1) The user requests access to a service offered by a SP. The user device does not include any  
 600 authentication credentials.
- 601 2) Since access to this service requires the User to be authenticated but the request in step 1 does  
 602 not include any authentication credentials, the SP sends an Authentication Request to the IdP.  
 603 This Authentication Request may be passed to the IdP via the user device using redirection.
- 604 3) The IdP checks the Authentication Request received in step 2, and - as the SP is new to the IdP's  
 605 circle of trust - the IdP determines that it does not have an identifier stored in its database for the  
 606 User for the given SP.  
 607 Conventionally, the IdP would respond to the Authentication Request by issuing an error  
 608 message or a randomly generated identifier. This, however, is problematic: In the former case,  
 609 the service access request in step 1 breaks down. In the latter case, the SP has to ask the user  
 610 for his credentials and then send (usually via a backchannel) a message to the IdP indicating that  
 611 from now on the IdP should use the "real identifier" instead of the random one for the given user  
 612 (this could be done via the NameIdentifier Management Protocol).
- 613 4) This step is not defined in SAML V2.0: Since the IdP has realized in step 3 that it does not have  
 614 an identifier for the combination of the User and the SP, the IdP generates a message called  
 615 Name Identifier Request and sends it to the SP.
- 616 5) Upon receipt of the Name Identifier Request, the SP recognises that the IdP does not have an  
 617 identifier for the combination of SP and User. Therefore, the SP prompts the User to log in to the  
 618 SP.

- 619 6) This step is also not defined in SAML V2.0: The SP sends a message called Name Identifier  
620 Response to the IdP. This response message includes the identifier for the combination of User  
621 and SP that the IdP is to use in any further communication and authentication processes.
- 622 7) On receipt of the Name Identifier Response, the IdP stores the identifier contained in the Name  
623 Identifier Response in its database. The IdP sends an Authentication Response to the SP, which  
624 uses the identifier received in step 6.
- 625 8) The SP grants the User access to the requested service.
- 626

## 627 **5.2.3 Perceived Technical issue**

628 This contribution aims at introducing a new SAML protocol called SAML Name Identifier Request protocol  
629 into the SAML 2.0 specifications.  
630

## 631 **5.3 SAML Attribute Management Request**

### 632 **5.3.1 Scenario/context**

633 More and more services and applications are becoming available on the Internet, and many of these  
634 services and applications require authentication. With the convergence of telco and Internet domain, the  
635 telco has added functionality, namely IDM functions. The telco operator will collaborate with several SPs,  
636 that in return depend on the telco's profile and attribute store. This causes a scenario where not the SP  
637 manages the attributes, but the telco operated IDM.

638 One approach that has been developed to assist users to access multiple services and applications, each  
639 requiring separate authentication procedures, involves the use of identity federation.

640

641 Security Assertion Markup Language (SAML) is an XML standard for exchanging authentication and  
642 authorisation data between security domains. For example, SAML is used for exchanging assertion data  
643 between an identity provider (a producer of assertions) and a service provider (a consumer of assertions).

644

645 The issue highlighted in this section aims at possibly extending the SAML specifications.

646

### 647 **5.3.2 Use Case**

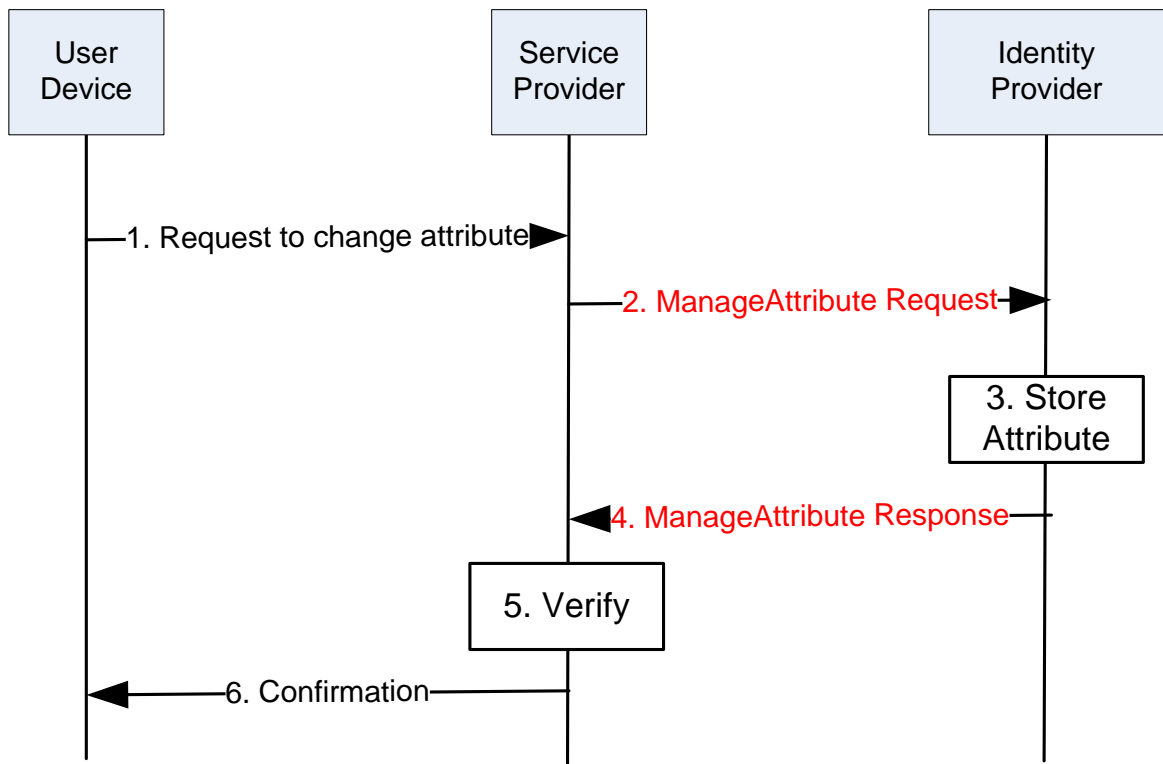

648 A user wishes to use his attribute information across multiple service providers, such attribute information  
649 can be layout, preferred email address, etc. Today, these attributes are stored locally at each of service  
650 provider. Thus, user will have to enter and changes the same attributes multiple times in order to ensure  
651 they are consistent for each of the different service providers the user has an account with, resulting in a  
652 bad user experience.

653

654 The user creates a temporary or transient account. The service provider allows the user to set specific  
655 settings like coloring, text size, etc. But he/she does not want to set these setting again each time the  
656 user logs in because the service provider will not be able to link the attributes for a user's temporary  
657 account with the user's permanent account. This is because by the very nature of a temporary or  
658 transient account the next time the user logs on to the service provider the user will have a different  
659 username and so the service provider will not be able to link the attributes for a user's temporary account  
660 with the user's permanent account.

661

662 Figure 14 provides a high-level message flow outlining the proposed SAML Attribute Management  
663 protocol:

664  
665

Figure 14: "SAML Attribute Management request" use case: pictorial representation

667

668 The ManageAttribute Request and Response messages are marked in red since the SAML 2.0 does not  
669 support such messages yet. The ManageAttribute Request allows the Service Provider to manage  
670 attributes stored on the Identity Provider side. As an example, the following XML instance of a  
671 ManageAttribute Request asks the Identity Provider to set the value of the "mail" attribute to  
672 "trscavo@gmail.com":

673

674 The following example shows what such a change in the specification would enable to do:

675 `<samlp:ManageAttributeRequest`

676 `xmlns:saml="urn:oasis:names:tc:SAML:2.0:assertion"`

677 `xmlns:samlp="urn:oasis:names:tc:SAML:2.0:protocol"`

678 `ID="aaf23196-1773-2113-474a-fe114412ab72"`

679 `Version="2.0"`

680 `IssueInstant="2006-07-17T20:31:40Z">`

681 `<saml:Issuer`

682 `Format="urn:oasis:names:tc:SAML:1.1:nameid-`

683 `format:X509SubjectName">`

684 `C=US, O=NCSA-TEST, OU=User, CN=trscavo@uiuc.edu`

685 `</saml:Issuer>`

686 `<saml:Subject>`

```

687     <saml:NameID
688         Format="urn:oasis:names:tc:SAML:1.1:nameid-
689 format:X509SubjectName">
690         C=US, O=NCSA-TEST, OU=User, CN=trscavo@uiuc.edu
691     </saml:NameID>
692 </saml:Subject>
693 <saml:AttributeStatement>
694     <saml:Attribute
695         xmlns:x500="urn:oasis:names:tc:SAML:2.0:profiles:attribute:X500"
696         x500:Encoding="LDAP"
697         NameFormat="urn:oasis:names:tc:SAML:2.0:attrname-format:uri"
698         Name="urn:oid:1.3.6.1.4.1.1466.115.121.1.26"
699         FriendlyName="mail">
700     <saml:AttributeValue
701         xsi:type="xs:string">trscavo@gmail.com</saml:AttributeValue>
702     </saml:Attribute>
703 </saml:AttributeStatement>
704 </samlp:ManageAttributeRequest>
705

```

### 706 5.3.3 Perceived Technical issue

707 The SAML protocol currently provides two methods that enable *a service provider to retrieve attributes*  
708 relating to a user *from identity provider*:

709

- 710 • The first method is an attribute push method in which the identity provider can send attribute  
711 information within the SAML assertion provided in response to the service provider's user  
712 authentication request.
- 713 • The second method is an attribute pull method in which the service provider can use an  
714 AttributeAuthority message or an AttributeQuery message to retrieve information regarding user  
715 attributes from the identity provider once the user has been authenticated by the identity provider.

716

717 → In both methods described, the service provider can only obtain information relating to the attributes of  
718 the user logged into the service provider.

719 → There currently exists no mechanism to enable *a service provider to transmit user attributes to be*  
720 *stored at the identity provider*. This contribution identifies the use case of such mechanism.

721

722 The issue highlighted in this section aims at possibly extending the SAML specifications.

723

## 724 5.4 User ID Forwarding

### 725 5.4.1 Scenario/context

726 The issue presented in this section derives from a concrete case of activities performed by an operator in  
727 order to define and implement a "security architecture" for its SOA middleware infrastructure.

728 This section addresses potential issues within the OASIS Web Services Security specification ([WS-S  
729 1.1].

730 Specifically such issues/limitations are related to the necessity of forwarding the User ID across the SOA  
731 Infrastructure.

732

## 733 5.4.2 Use Cases

734 In order to better describe the potential technical issues, hereafter a use case is presented (ref. Figure  
735 15), with two possible different example scenarios. The use case is that of a Web Service exposed by an  
736 Application Provider, and the scenarios are:

- 737 • Customer Care portal accessed by both operator customers and personnel (Call Center Operators),  
738 each of them having different “rights” on accessed data.
- 739 • Telco Messenger Service accessed by different MVNOs (Mobile Virtual Network Operators), each of  
740 them having different “rights” on accessed data.

741

742

### 743 Use case Description

744

745

746

747

Figure 15: User ID Forwarding use case

748

- 749 1. User 1 accesses a front-end application (C1) using his Credentials (i.e. SSO Token).
- 750 2. C1 invokes a Web Service (WS-A) exposed by P1 and passes the User’s credentials (i.e. SAML  
751 Assertion) and its credentials (i.e. X.509 Certificate) for XML Encryption and XML Signature (WS-  
752 Security 1.1).
- 753 3. S1 (Security Enforcement Point) handles the invocation message and enforces the AAA policies:  
754 a. It validates C1 X.509 Certificate.  
755 b. It verifies the XML Encryption and Signature using the public key of C1.  
756 c. It verifies if C1 is authenticated & authorized to access the WS-A (C1 X.509 Certificate).  
757 d. It verifies if the SAML Assertion and User’s token are still valid.  
758 e. It verifies if User 1 is authenticated & authorized to access WS-A.
- 759 4. P1 (Provider) runs the business logic.

760

### 761 5.4.2.1 Customer Care portal accessed by both operator customers and 762 personnel (Call Center Operators)

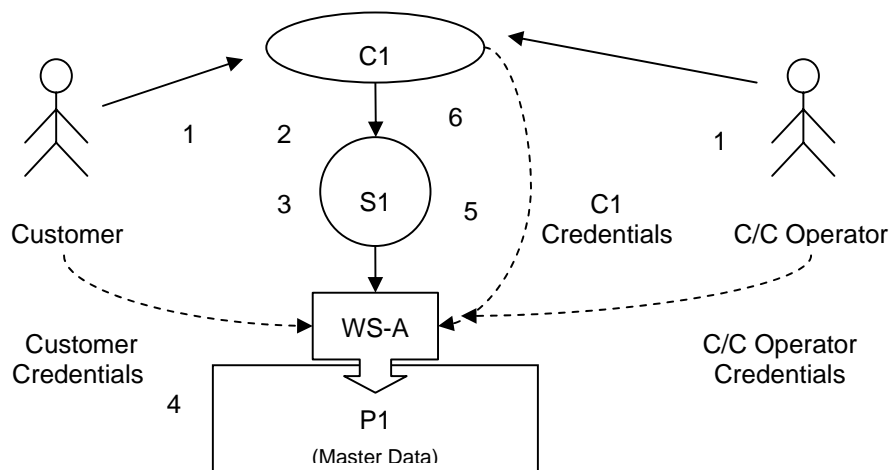

763 C1 is a Portal for Customer Caring that consumes a Web Service (WS-A) for retrieving profile information.  
764 It is used by both Customers (for Self Caring) and Call Center Operators (ref. Figure 16).

765 Some of the available information such as: incoming and outgoing calls, personal information or credit  
766 cards details are ruled by privacy policies.

767 Obviously WS-A and all its operations are accessible by C1 but information provided as result or specific  
768 details depend on the original requester: a Customer could have full access on all information and details  
769 available on its profile while a Call Center Operator could be granted to view only a subset such data (i.e.  
770 partial call numbers, filtered credit cards details, etc.).

771 In the following scenarios C1 invokes WS-A for retrieving the list of incoming call numbers for specific  
772 customers:

773

774

775

776 Figure 16: User ID Forwarding – “Customer care” use case

777

#### 778 Scenario 1 (Operator’s Customers)

- 779 1) A Customer accesses C1 to view the list of outgoing calls by using his Credentials (i.e. SSO  
780 Token).
- 781 2) C1 invokes a Web Service (WS-A) exposed by P1 passing the Customer’s credentials in a SAML  
782 Assertion and using its X.509 Certificate for XML Encryption and XML Signature (WS-Security  
783 1.1).
- 784 3) S1 (Security Enforcement Point) handles the invocation message and enforces the AAA policies:  
785 a. It validates C1 X.509 Certificate,  
786 b. It verifies the XML Encryption and Signature using the public key of C1,  
787 c. It verifies if C1 is authenticated & authorized to access the WS-A (C1 X.509 Certificate),  
788 d. It verifies if the SAML Assertion and User’s token are still valid,  
789 e. It verifies if operator Customers is authenticated & authorized to invoke WS-A and what  
790 level of information could access.
- 791 4) P1 (Provider) runs the business logic.
- 792 5) S1 receives the result from P1 and applies all the privacy policies in order to then return the data  
793 to C1
- 794 6) C1 shows the entire results to Customers such as:

795

796 03/27/09 11:39 3355799553 05:37

797 03/27/09 12:03 3359955125 10:57.

798

799

800

### Scenario 2 (Call Center Operator)

801 1) A Call Center Operator accesses to view the list of incoming call numbers for a specific customer  
802 by using his Credentials (i.e. SSO Token).

803 2) C1 invokes a Web Service (WS-A) exposed by P1 passing the Operator's credentials in a SAML  
804 Assertion and using its X.509 Certificate for XML Encryption and XML Signature (WS-Security  
805 1.1).

806 3) S1 (Security Enforcement Point) handles the invocation message and enforces the AAA policies:  
807 a. It validates C1 X.509 Certificate,  
808 b. It verifies the XML Encryption and Signature using the public key of C1,  
809 c. It verifies if C1 is authenticated & authorized to access the WS-A (C1 X.509 Certificate),  
810 d. It verifies if the SAML Assertion and User's token are still valid,  
811 e. It verifies if C/C Operator is authenticated & authorized to invoke WS-A and what level of  
812 information could access.

813 4) P1 (Provider) runs the business logic.

814 5) S1 receives the result from P1 and applies all the privacy policies in order to then return the data  
815 to C1.

816 6) C1 shows the entire results to C/C Operator such as:

817

818 03/27/09 11:39 3355799XXX 05:37

819 03/27/09 12:03 3359955XXX 10:57

820

### 5.4.2.2 Telco Messenger Service accessed by different MVNOs (Mobile Virtual Network Operators)

821 An operator has released a new integration layer called "Services Exposure" (SE) dedicated to supply all  
822 possible services (Telco, OSS and BSS) needed to any MVNO. At the moment the operator has 2 MVNO  
823 customers which consume more or less the same services, but with different policies and SLAs ruled by  
824 specific service contracts (ref. Figure 17).  
825  
826

827

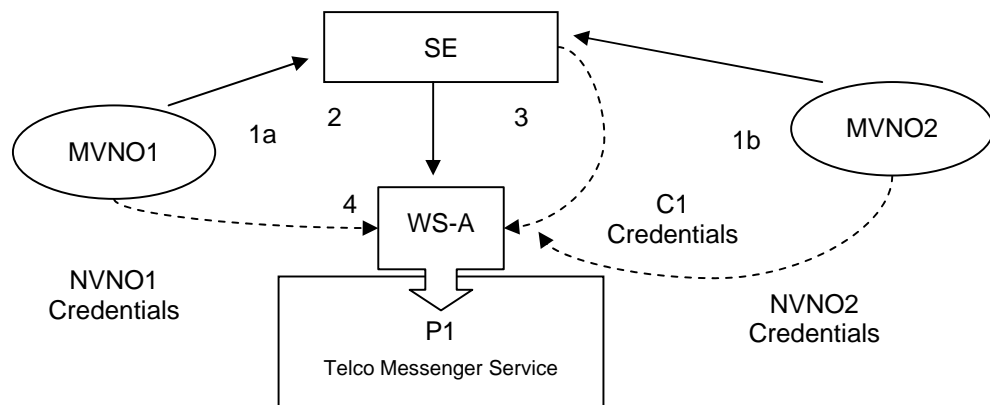

828 The possibility to uniquely identify the MVNO that is using a service and enforce ad-hoc policies becomes  
829 essential to enable the operator to guarantee those contracts.

830 In addition to that all services exposed by the Service Exposure are potentially consumable by any other  
831 operator application. Therefore the possibility to identify also the application consumer is strong  
832 requirement for an operator.

833

834 In the following scenario MVNO1 and MVNO2 invoke WS-A to send messages to their customers, but  
835 while MVNO1 can send all types of messages (i.e. SMS, Reliable SMS, MMS, email, etc.), MVNO1 can  
836 send only SMS and MMS:

837

838  
839  
840  
841  
842  
843  
844  
845  
846  
847

Figure 17: User ID Forwarding – "MVNO" use case

- 1) MVNO1 and MVNO2 invoke a service exposed by SE for sending messages.
- 2) SE enforce the AAA policies based on services contracts specific for each MVNOs.
- 3) SE verifies which types of messages MVNO1 and MVNO2 can send.
- 4) SE forwards the invocations to WS-A using its credentials (i.e. X.509 Certificate) and including the MVNO credentials (i.e. SAML Assertion).

### 848 5.4.3 Perceived Technical issue

849 At the moment it seems to be impossible to add two (or more) credentials in one message.

850

851 OASIS WS-Sec specifications **[WS-S 1.1]**, Section 6, "Security Tokens" rows 717 and 719, may offer a possibility to address the issue.

852

853 In row 717 and following it is stated:

854 *717 /wsse:UsernameToken/wsse:Username/@{any}*

855 *718 This is an extensibility mechanism to allow additional attributes, based on schemas, to be*

856 *719 added to the <wsse:Username> element.*

857

858 While in row 791 and following it is stated:

859

860 *791 /wsse:BinarySecurityToken/@{any}*

861 *792 This is an extensibility mechanism to allow additional attributes, based on schemas, to be*

862 *793 added.*

863

864 In any case, the solution proposed by specifications is not sufficient because, even allowing the addition of an attribute, e.g. an "Original Requester" in the specific use case, such addition would not solve the issue because it would be anyway necessary to agree the schema (protocol) amongst all actors involved in the SOA infrastructure (provided by different vendors, etc.).

865

869 This would inevitably lead to the necessity of a high customization (and consequent expenditure) of the  
870 security models.

871

872 In order to avoid costly, non-standard, vendor/platform dependent customizations and ad-hoc  
873 agreements, the operator considers that it is opportune to standardize such "protocol".

874

---

## 875 6 Issues on Management

876

### 877 6.1 Introduction

878 The purpose of this section is to introduce to OASIS SOA-Tel TC requirements related to Service  
879 Interface cardinality and definition of metadata for Service Lifecycle Management as they emerge from  
880 the specification work in TeleManagement Forum Service Delivery Framework (SDF) program  
881 (<http://www.tmforum.org/ServiceDeliveryFramework/4664/home.html>).

882

883 This section addresses:

- 884 • potential limitations in the OASIS specifications that have been considered when analyzing the  
885 architectural patterns and possible implementations (such as SOA) for SDF's distributed capabilities,  
886 specifically OASIS SOA-Reference Model [**SOA RM 1.0**] and SCA Assembly Model [**SCA Assembly**  
887 **1.1**].
- 888 • potential updates to OASIS SOA Reference Architecture [**SOA RA 1.0**] as a result of the specification  
889 work developed in TM Forum SDF team, specifically:
  - 890 - additional Service Management Interface,
  - 891 - additional metadata for the support of Service Lifecycle Management.

892

### 893 6.2 Scenario/context

894 The context from which this proposal originates is the modeling and specification activities that  
895 TeleManagement Forum is performing in order to define a Service Delivery Framework. The results are  
896 published in TM Forum's SDF Reference Model (TR139v2) and SDF Reference Architecture (TMF061)  
897 documents, available to TM Forum's Members.

898

899 The TM Forum SDF objective is to manage end to end the lifecycle of services including cases where  
900 services have dependencies they can not manage and cases where services are the result of dynamic  
901 and static composition across service ownership/governance domains.

902

903 A Service Delivery Framework must respond to most actual management needs of Service Providers  
904 while Services increasingly diversify:

- 905 • manage a Service the same way, whether it comes from network, web or IT resources,
- 906 • manage a Service the same way, whether it is retailed, wholesale or operated in-house,
- 907 • manage compositions of Services when each Service may be owned by separate entities  
908 (organizations, Service or Content Providers), including the relationship that must exist among these  
909 entities,
- 910 • manage multiple versions of a Service.

911

### 912 6.3 Services exposing Management Interface

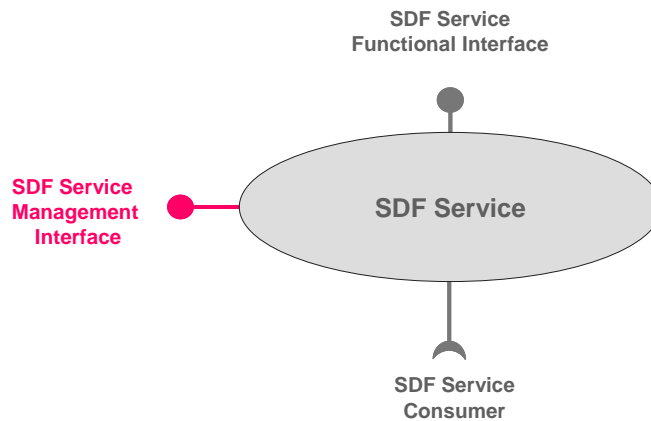

913 The complexity of Service Providers business and operations requires a Service to be managed close to  
914 the context in which it is used in order to understand who is using the service, eventually change service  
915 parameters to adapt to its usage, measure in real-time the quality of each interaction with the service,  
916 check on service status, etc.

917 A Service may have multiple capabilities, some of which may be used for functional purposes some for  
918 management purposes, depending on the context in which the service is used.

919

920 To fulfill TM Forum SDF's goal of E2E service lifecycle management, the TM Forum SDF team considers  
921 as Service model one where the Service exposes its manageability capabilities by means of a specific  
922 Interface, following the pattern in Figure 18.

923

924

925

926

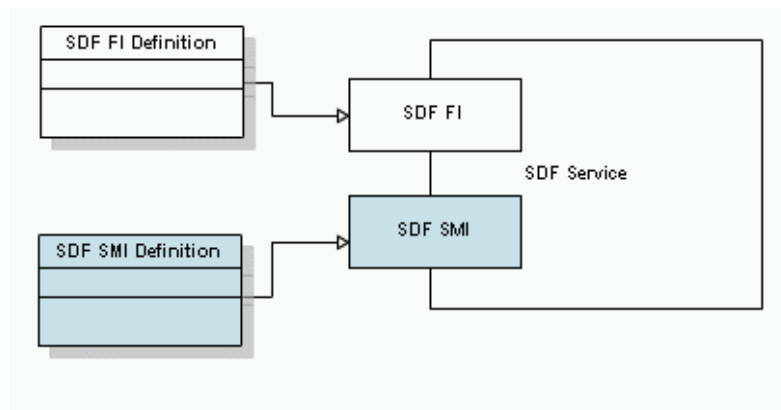

Figure 18: TM Forum "SDF Service"

927

928 In this model, the SDF Service capabilities are exposed and consumed through the SDF Functional  
929 Interfaces (SDF FI) while the management capabilities/operations of the SDF Service are available  
930 through the SDF Service Management Interface (SMI). SDF Service may consume other Services  
931 through yet another, consumer type, interface (ref. Figure 19).

932

933

934

935

Figure 19: Including management capabilities definition in the SDF Service description

936

937 The reasons for the separation and exposure of manageability capabilities at another interface (SMI) are:

- 938 • Management capabilities are consumed by other type of (specialized) consumers (e.g. support  
939 services) with different policy/security rules than consumers of functional capabilities

- 940 • Some higher level operations and business around services can be simplified by ignoring  
941 “layers/levels” at which functional capabilities of services may be embedded, and access directly  
942 their management capabilities.  
943

### 944 6.3.1 Perceived Technical Issues

945 The OASIS documentation defines Services in SOA RM and Service Components in SCA as if the  
946 cardinality of Service Interface is 1 and only one.

947 -----

948 **[SOA-RM 1.0]:** (Section 3.1) “A service is accessed by means of a service interface (see Section  
949 3.3.1.4), where the interface comprises the specifics of how to access the underlying capabilities.”

950 **[SOA-RM 1.0]:** (Subsection 3.3.1.4) “**The** service interface is the means for interacting with a  
951 service.”

952 **[SCA Assembly 1.1]:** “A Service represents an addressable interface of the implementation.”  
953 Note – SCA definition for Service may be a consequence of the SOA-RM definition, we do not  
954 know

955 -----

956 Moreover, for those implementers who use WSDL to describe services, the W3C **[WSDL 2.0]** primer  
957 document, (section 5.4) states that, “wsdl:service specifies only one wsdl:interface ()”.

958 We are aware of the solutions presented by W3C but these solutions are not standardized.

959

960 Following these documents it seems to be impossible to have two or more interfaces for a SOA Service.  
961 At the same time, SOA RA document acknowledges that “In fact, managing a service has quite a few  
962 similarities to using a service” hinting that a management of a service should happen at an interface. The  
963 same document offers though another solution (separation between management services and non-  
964 management services) which we will discuss in the next use case.

965 -----

966 **[SOA-RA 1.0]** (3137 – 3140) “In fact, managing a service has quite a few similarities to using a  
967 service: suggesting that we can use the service oriented model to manage SOA-based systems  
968 as well as provide them. A management service would be distinguished from a non-management  
969 service more by the nature of the capabilities involved (i.e., capabilities that relate to managing  
970 services) than by any intrinsic difference. “

971 -----

972 Today many management capabilities are bundled with the functional interface of the service description  
973 which makes management of services very hard. This situation poses a problem for suppliers who would  
974 like to follow a SOA path for their SDF solutions. For example,

- 975 • how can they take already existing SOA Services and make them SDF Services?  
976 • Can a SOA Service work with a Management Interface and a Functional Interface?

977 In TM Forum, the MTOSI team created multiple (coarse and fine grain) web services as alternative to  
978 multiple interfaces (<http://www.tmforum.org/BestPracticesStandards/mTOPMTOSI/2319/Home.html>).

979 There is a need to specify that all these WS-es are related (e.g. allow access and interaction with the  
980 same Inventory and its elements).

981

982 TM Forum SDF team is seeking reconciliation on this matter and asks about possibilities to express the  
983 SDF Service and its SMI using SOA Service model.

984

985 TM Forum SDF team is also seeking alignment of its SMI addition to a Service model with the work  
986 developed in OASIS WSDM – MOWs.

987

988

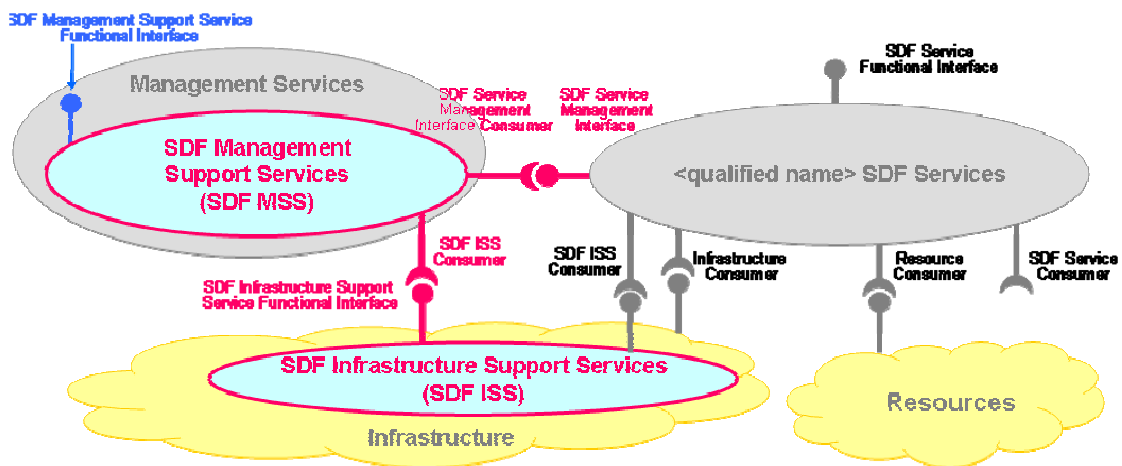

## 989 6.4 Metadata in support of Service Lifecycle Management

990

991 In TM Forum’s SDF Reference Model (ref. Figure 20) (ref. TM Forum TR 139 v 2) the lifecycle  
992 management of an SDF Service is supported by other services created to fulfill the needs of business and  
993 operational processes.

994

995

996

997

998

999

Figure 20: SDF Reference Model

- 1000 • **SDF Management Support Service (SDF MSS):** An SDF Management Support Service (SDF MSS)  
1001 consumes the SDF SMI of a SDF Service to manage the SDF Service. Examples of SDF MSS-es are  
1002 Activation/Configuration, Problem management, Service Quality Management.
- 1004 • **SDF Infrastructure Support Service (SDF ISS):** An SDF ISS provides reusable functionalities,  
1005 exposed via functional interface(s), to support the SDF. Examples of possible SDF ISS are:  
1006 Catalogues, Metadata repository, User Profile.

1007

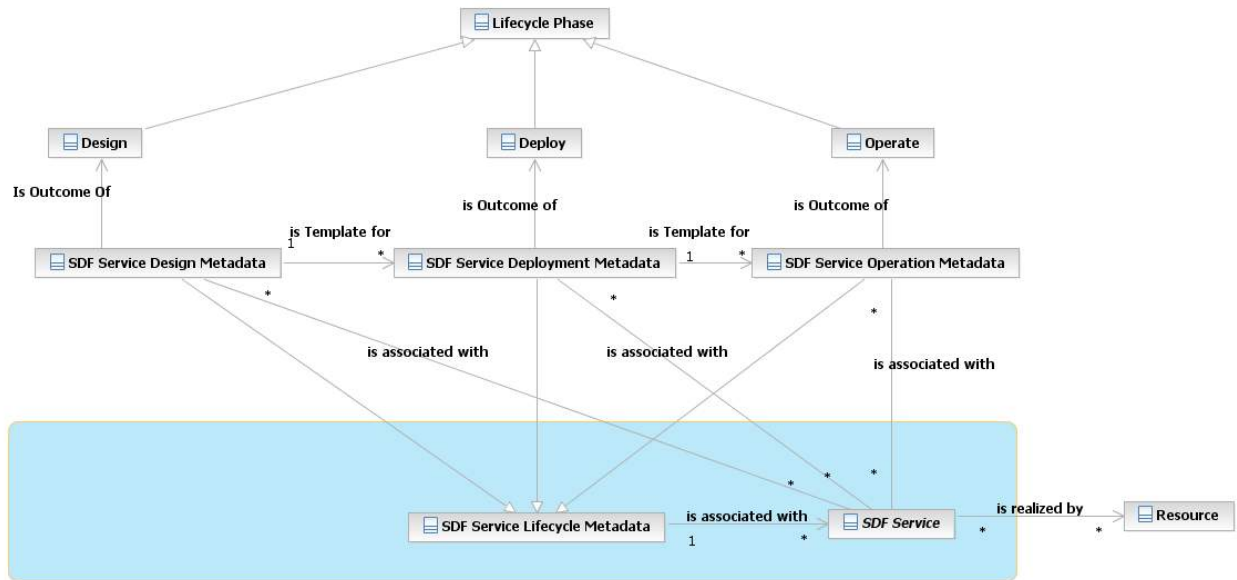

1008 In agreement with the OASIS [SOA RA 1.0] (3137 – 3140) paragraph mentioned in section 6.3.1, SDF  
1009 RM shows that these supporting services are of the same nature as the SDF Service itself, the only  
1010 difference is that they “manage” or help in managing the SDF service (e.g. helping is the role of ISS  
1011 Services). But these services need to be managed at their turn. For this reason, SDF Support Services  
1012 follow the same pattern as the SDF Service: they have both **a functional and a management interface**.

1013

1014 Specialization in supporting and managing a service during its whole lifecycle requires finer granularity  
1015 knowledge about that service: properties, supported actions or operations, possible states as well as  
1016 contracts that may govern interactions with the service (including pre and post conditions for these  
1017 interactions), what is the “architectural” style for service “composability”, what are its dependencies or  
1018 what is the level of exposure for its functional capabilities.

1019 The proposed model for the TMF SDF SDF Service is complemented by additional data representation  
1020 (metadata) in support of SDF Service lifecycle management (ref. Figure 21 and Figure 22). This new data  
1021 representation containing information about the service in various phases of its lifecycle, aims at covering

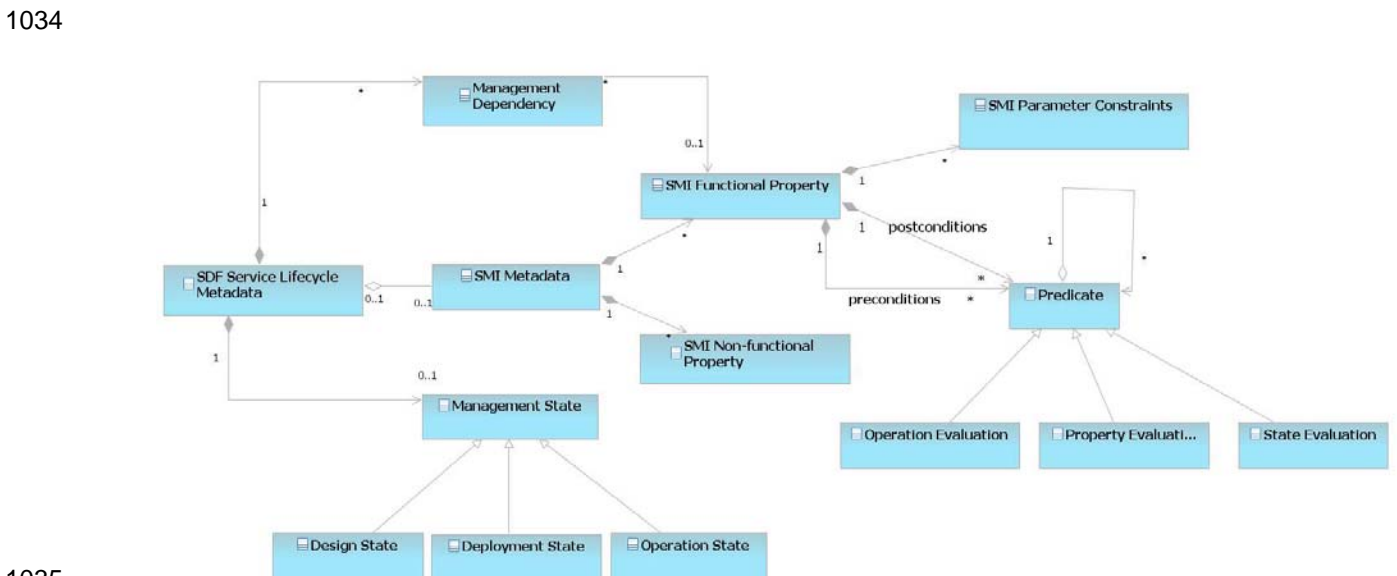

1022 current gaps in the information available for the purpose of service management (e.g. what is already  
 1023 covered by the SOA Service description) in the overall context of Service Provider's business and  
 1024 operations. Moreover, this metadata is dynamic: it may change from one phase to another of the SDF  
 1025 Service lifecycle.  
 1026

1027  
 1028 Figure 21: SDF Service lifecycle phases and associated metadata

1029  
 1030 The SDF Service Lifecycle Metadata consists at least of:

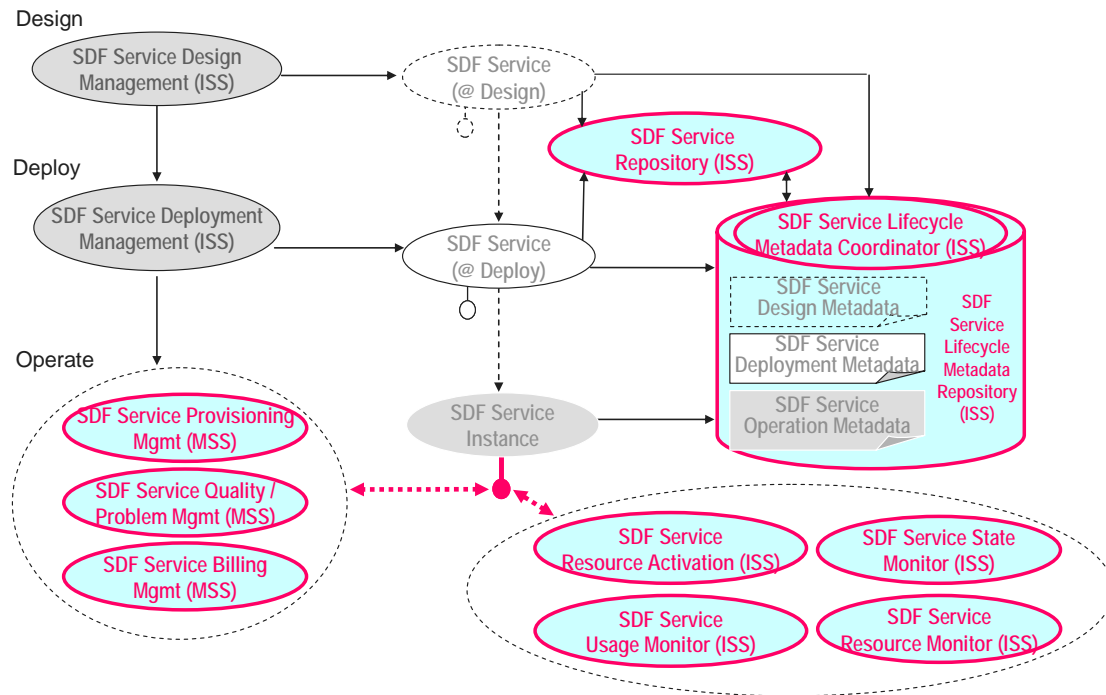

- 1031 1. **Additional information about the SMI of a SDF Service** (properties, actions);
- 1032 2. **Management Dependencies of the SDF Service**, including cross-domains dependencies;
- 1033 3. **Management State** of the SDF Service.

1035  
 1036  
 1037 Figure 22: SDF Service Metadata (concepts)

1038  
1039  
1040  
1041

The way this metadata is used by SDF Supporting Services to manage an SDF Service during its lifecycle is depicted below (ref. Figure 23).

1042  
1043  
1044  
1045

Figure 23: Service Lifecycle Management through SDF

#### 1046 6.4.1 Perceived Technical issues

1047 The purpose of TM Forum work is not to duplicate existing work but to add to it that part that is necessary  
1048 for service lifecycle management. The information representation (metadata) that TM Forum SDF team  
1049 has identified as necessary for SDF Service Lifecycle Management, as well as its evolving nature, do not  
1050 seem to be modeled in the current SOA Service Description Model and supported by the Management of  
1051 Services approach described in [SOA –RA 1.0] document. TM Forum SDF Team believes that modeling  
1052 service dependencies including dependencies across ownership/governance domains is important  
1053 addition to the SOA RA.

1054  
1055 TM Forum SDF team is seeking OASIS expert advice on what to do. Can the additional metadata it  
1056 specifies for the purpose of SDF Service lifecycle management be added to the current [SOA RA 1.0], in  
1057 respect to the views and the models that are already part of this Reference Architecture?

1058  
1059 TM Forum SDF team is also seeking OASIS expert advice on aspects such as supporting versioning and  
1060 compatibility of this metadata, existing architectural patterns for data contribution from various  
1061 applications/sources/systems and for assurance of cohesiveness across metadata elements and along  
1062 the phases in the lifecycle of a service.

1063

1064 **6.5 Recap of issues and considerations for OASIS SOA-Tel analysis**

1065 TM Forum SDF team is seeking reconciliation on the matter of the additional service management  
1066 interface and asks about possibilities to express the SDF Service and its Service Management Interface  
1067 (SMI) in the SOA Service model. TM Forum SDF Team believes that distinguishing the SMI from the  
1068 Functional Interface of a Service is necessary for the reasons exposed in the use case.

1069 What is OASIS's advice on this and how can SDF Service model be realized with current SOA Services  
1070 Model?

1071

1072 TM Forum SDF team is also seeking OASIS expert advice on positioning of its SMI addition to a Service  
1073 model within the work developed in OASIS WSDM – MOWs.

1074

1075 TM Forum SDF team is also seeking OASIS expert advice on what should be the relationship between  
1076 the SDF Reference Model and the SOA Reference Architecture - Service as Managed Entities part.

1077

1078 TM Forum SDF team is seeking OASIS expert advice on how to organize and integrate the additional  
1079 metadata for the purpose of SDF Service lifecycle management in the current **[SOA RA 1.0]** and do so  
1080 with respect to the views and the models which are already part of this RA.

1081

1082 TM Forum SDF team is also seeking OASIS expert advice on aspects such as supporting versioning and  
1083 compatibility of metadata, existing architectural patterns for data contribution from various  
1084 applications/sources/systems and for assurance of cohesiveness across metadata elements and along  
1085 the phases in the lifecycle of a service.

## 7 Issues on SOA collective standards usage

### 7.1 Common Patterns for Interoperable Service Based Communications

#### 7.1.1 Scenario/purpose

There is a growing set of application models that serve a general web and mobile market and consequently can only expect a web application pattern and can not make any assumptions of the protocol stack other than IP. These applications are no longer exclusive to the public domain. Applications in the enterprise are adopting these new computing models, seamlessly moving between internal and external clouds trying to leverage the elasticity that the model offers and blending application oriented communications across these boundaries. Such applications are typically designed to support highly functional virtual and often transient partner/ end user/ customer relationships.

Users in these models expect access to information anytime, anywhere and will expect the enablement of communications within that context of any application to be delivered in the same way. Ubiquity of communications as a part of this set of internet type applications, LAN attached or mobile, needs to allow for interoperation across a definable set of standards and device types in order for it to achieve the same universality as the supporting application models, bringing seamless communications utility across different communication domains and applications.

In such models, the application can only make general assumption about the device attributes and protocol stacks these devices support. Ubiquity of communication within the application model calls for device information and communications channel setup to be ascertained thru the process of user/ device connecting to the application. In some situations the application may not be directly involved in setting up media, in other cases it will either need to participate, at least in part or entirely. An application may even have to make decisions as to the best choice of path of delivery.

Achieving ubiquitous access to application resources irrespective of network domain is often a function a combined collection of standards working in unison (i.e. profile) providing consistent patterns to access applications resources. Consistency in approach across different media and control paths, client types and application domains is essential to foster larger a eco-system of co-operative applications for the user across different network and application domains. Hence, the patterns supporting the discovery, setup and delivery of communications within the context of a set of applications needs to be normalized in order to enable interoperable solutions across heterogeneous environments.

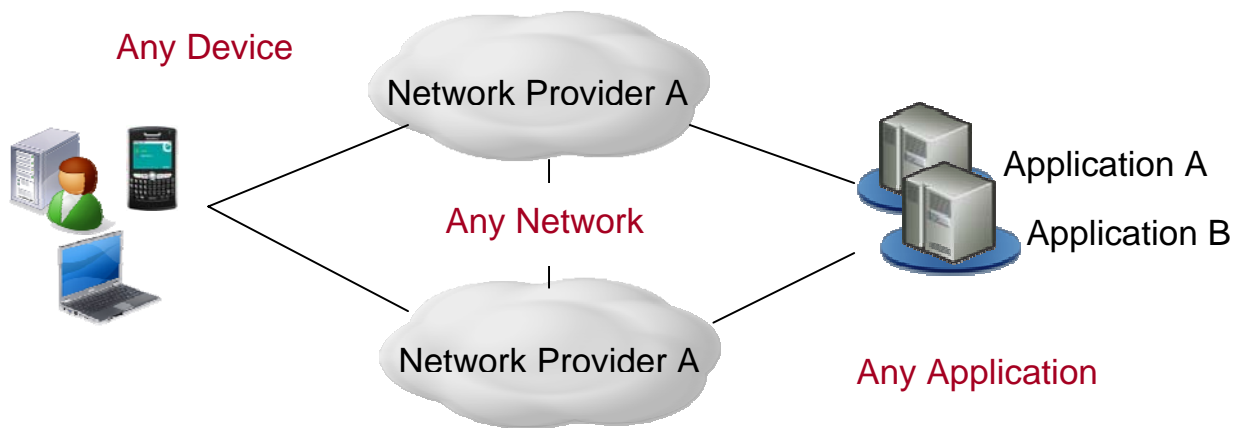

Enclosed is an example:

- An Independent collision appraisal company has independent collision agents that broker across separate suppliers on behalf of many insurance companies, auto suppliers and collision repair shops. The agents choose which suppliers to use based on their locale and relationships but these are under a lot of change.
  - No one company owns and controls the type of agent device.
  - Agents typically search a few supplier sites for any given situation. They expect to be able to quickly call and have the context of the part/order be available to any parts supplier, insurance company and collision shop they use. The agent may further use media (picture, video) to support and verify the parts needed with the supplier.
  - The applications from different companies support different service profiles (voice, video, picture, and data) to deliver the capability. Real Time communications is supported thru variable means including but not limited to, SIP, Jingle or simply an RTP stream controlled directly by the application.

1135                   o A standard means application communications profile needs to be delivered in order to  
1136 allow any agent and device to work in the context of a set of independent applications  
1137 from different suppliers  
1138

1139 The market in general needs a normalized means to establish communications to the endpoint without  
1140 being prescriptive at the endpoint. Applications need greater control over the different choices to be made  
1141 given multiple network paths and options. An application requesting a connection should be able to adapt  
1142 seamlessly to the network environment and protocols used to set up the communications channels. In  
1143 addition, external tools such as BPEL, BPM and ESB should be able to leverage this common foundation  
1144 to incorporate communications processing. This is important for broader adoption of communication as a  
1145 service using well known patterns and skills. Figure 24 depicts the case.  
1146

1147

1148  
1149  
1150 Figure 24: Real-time communications in the context of an “any” application seamlessly across any device  
1151 and network  
1152

1153 The following is a minimum set of requirements:

- 1154
- 1155 1. **Universal service discovery/ dynamic bindings**
  - 1156 2. **Bi-directional, full duplex control across different modes of communication thru web**  
1157 **service interfaces**
  - 1158 3. **Common support for asynchronous interactions with event subscriptions and**  
1159 **notifications**
  - 1160 4. **Means to associate application context with stateful communication interactions (i.e.**  
1161 **session)**
  - 1162 5. **Common communication information model enabling connection negotiation.**
  - 1163 6. **Common patterns for client web services to work within a SIP and XMPP context.**
    - 1164 o **Integrated control of media delivery (transport channels and their parameters)**
    - 1165 o **Control of communications channel, events for that session**
- 1166

1167 Items 1, 2, 3 and 4 above target a common set of web service infrastructure requirements to generically  
1168 set up communications. Items 5 and 6 are essential to handle differences (e.g., between a SIP or Jingle,  
1169 etc based endpoints) thru the service interface.

1170 **7.1.2 Scenario/context**

1171 This use case involves a simple web application that connects to the site, pulls down a list of people to  
1172 contact and allows the user to click-to-call. Assume a simple model where JavaScript is downloaded to  
1173 the client and sets up the web service call to a communication service with the URI provided. The  
1174 sequence diagram in Figure 25 depicts the case.

1175 The use case defines a simple setup of a voice connection for one side of the connection. More complex  
1176 types of communication scenarios (e.g. conferencing, video) and multi-modal interactions (e.g. voice with  
1177 chat sessions) should be supported with the same pattern. All applications need a common means to set  
1178 up different ports supporting different types (voice, pictures) or multiplex thru one port but can not assume  
1179 one standard or protocol stack is at play as they do not know who and what type of device is going to  
1180 connect. A server based model implies that communications is handled at the server (i.e. server connects  
1181 client A to client B) where as the client model is more p2p. Each mode must be generally supported by  
1182 the pattern.

1183 The pattern discussed in this use case can equally be applied to REST type models using Restful API  
1184 mechanisms. This use case will confine itself to a web services client/ interaction model. It is important to  
1185 understand that whichever programming model used for the application, for generally application  
1186 interoperability across domain, the application model for communications needs to be consistent. Lastly,  
1187 some of the interface discovery complexity could be handled thru a commonly defined interface used  
1188 across vendors. Lack of such an agreed upon model, places more complexity in the meta-data needed to  
1189 describe what services handle what type of communications (i.e. voice or video connection, conference,  
1190 etc.) and more importantly describing the events types and data structures across the wire. This use  
1191 case does not go into detail the interactions for device attribute and/or interface discovery.

1192  
1193 **The basic interaction in this use case involves a web service interchange enabling the setup of a**  
1194 **communications channel exclusively. In this case we are selecting a communication channel that**  
1195 **is a proprietary RTP enabled socket controlled by the application. Hence, events need to be**  
1196 **exchanged to inform, negotiate and select the address on each side, the real time protocol used,**  
1197 **the codec and other pertinent information. The same negotiation process can be used to select a**  
1198 **SIP or XMPP/ Jingle based media channel when device attributes and condition warrant. In this**  
1199 **latter case, these protocols would negotiate the information on their own, freeing the service itself**  
1200 **from this activity.**

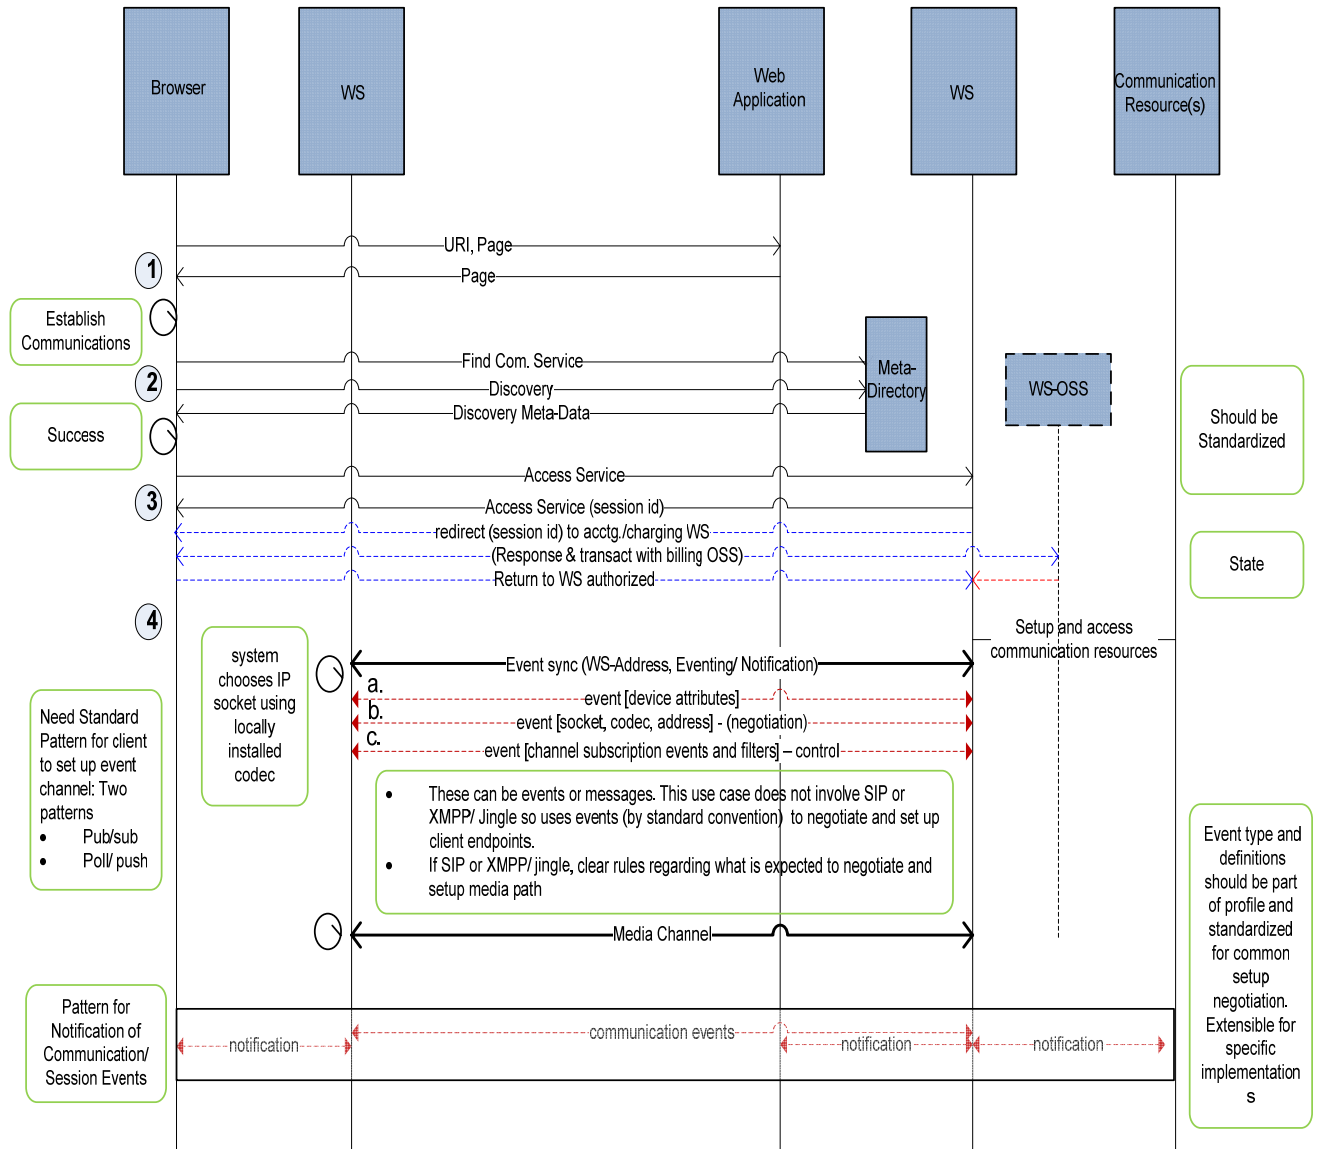

1201  
1202 Looking at this pattern we see that the set of requirements for the web services infrastructure (i.e.  
1203 standards) within the context of communications is clarified. We need a standard means to establish a  
1204 multimedia channel supporting real-time voice and video exclusively thru the web but also allow for  
1205 variation to support other approaches. This allows a higher degree of inter-operability across different  
1206 business and network domains. The standard pattern promotes common skills, behavior and tool  
1207 integration. It fosters development consistency, simplicity driving wider adoption and most important,  
1208 allows providers to offer solutions that work in the context of an inter-operable cloud.

1209

1210  
1211  
1212

**Use Case Sequence Diagram:**

1213  
1214  
1215

Figure 25: Sequence diagram example for the Universal Communication Profile case

1216 **Use Case Steps:**

- 1217 1. The communication responds back with a session id for the context of the application within a  
1218 communication channel.
- 1219 2. A bi-directional web services interface is set up to receive events for this session id.
- 1220 a. Client looks up service meta-data and discovers interface, binding, events and capabilities of  
1221 service. (i.e. WS- meta data and WS-policy)<sup>1</sup>.
- 1222 b. If there is no clear interface specification (i.e. CSTA, Parlay-x, other) then a very robust meta-  
1223 directory and policy infrastructure is needed to support the interface variations across  
1224 vendors.
- 1225 c. Connection is attempted. This may trigger events such as subscription authorization or pay-  
1226 as-you-go. This results in redirecting to a billing-OSS WS that engages the client over the  
1227 event-channel for payment methods and payment completion – leading to a notification and  
1228 return to the service-WS for further service delivery/denial<sup>2</sup>.
- 1229 3. Client connect to WS
- 1230 a. Event channel is set up.
- 1231 b. This event channel is overlaid with a subscription interface allowing each side to subscribe  
1232 and filter as necessary specific events needed for the communications.
- 1233 i. Model needs to support timely and reliable delivery of events
- 1234 ii. Model needs to support events delivered in specific order
- 1235 4. Client sends event indicating its device characteristics, communication modes (SIP, Jingle, etc.)<sup>3</sup>.
- 1236 a. Connection is made using “proprietary” socket. Application has designed the separation of  
1237 different types (i.e. picture, video, voice) and it manages the parsing and reformatting of each  
1238 for the application.
- 1239 i. User is in voice session
- 1240 ii. User is in transmitting pictures
- 1241 b. Server sends event indicating the mode it wishes to use given the device attributes.
- 1242 i. If SIP or XMPP/ Jingle client, negotiation of codec and address via those standards  
1243 but information (i.e. session description) is delivered to client application thru the web  
1244 service. The application sets up and controls the media, creates SDP response and  
1245 defines RTP port
- 1246 c. In this simple case we are using RTP with session description/ negotiation being handled thru  
1247 WS event channel.
- 1248 d. Client sends event to WS indicating what connection processing events it is interested in. In  
1249 this case it asks for connection, disconnect, hold/resume for picture and mute/un-mute for  
1250 events.
- 1251 e. Remote user presses hold for picture. Event is propagated to device and picture transmission  
1252 is held
- 1253

---

<sup>1</sup> Note: IETF work and SIP media and session policies stds (xml-based; can be realized as derived schema of the ws-policy core). Same goes for security policy (though ws-security-policy as it is restricted to only policies for ws-security standards.).

<sup>2</sup> This step is but an example interaction of several possible generic pre-communication events. In-communication and post-communication events are also conceivable.

<sup>3</sup> Note: Any WS-standards here or is it an area that the SOA-TEL TC can develop schema for?

1254 Since service architectures are inherently transport neutral, we can not rely on any underlying means (i.e.  
1255 TCP) to manage the session lifecycle. We do not imply any particular means in this example to establish  
1256 statefulness at either point across the wire, just a means to set up and convey the information across any  
1257 channel.

1258 It is our intention to first look to see if this is a common pattern across all communications services and to  
1259 identify the relevant standards that can be used and/or need to extend to support the need. Once  
1260 explored for web services we can extrapolate this to a common set of patterns for a broader set of service  
1261 interface types.

1262

### 1263 **7.1.3 Technical Issues/ Solutions:**

1264

1265 The purpose of the above uses case is not to prescribe a solution but what a solution may need to look  
1266 like in the context of the problem. The problem is basically that in order to deliver ubiquitous mobility and  
1267 interoperability to users, applications can not be bound by a single network provider nor underlying  
1268 assumptions on the real-time protocols used. Access to real-time communications needs to be  
1269 normalized across set of common access patterns in the context of any given application. The process is  
1270 not disjoint; application and communications need to work in context to deliver full effectiveness. Access  
1271 to the application resource requires the discovery the right pattern without any pre-defined assumptions  
1272 about the underlying network. The application also needs to be able to make decisions as to the best path  
1273 in multiple paths exist based on policy, cost, quality and device attributes.

1274

1275 Service orient architectures are in principle about decoupling the underlying transport form the delivery of  
1276 the application resource. This principle needs to be hold for access to applications / services and real  
1277 time communications used in the context of any application allowing for common access across a broad  
1278 set of applications.

1279

---

1280

## 8 Conformance

- 1281 The objective of this document is to collect potential technical issues and gaps of SOA standards utilized  
1282 within the context of communications service providers, in order to enable subsequent development of  
1283 requirements for the solution of such issues.
- 1284 As such no conformance clauses apply to this document.

1285

---

## Appendix C. Possible workaround related to issue in Section 3.1 “Transaction Endpoints Specification”

This section is non-normative.

This issue described within Section 3.1 could be solved with the following “workaround” solution, which in any case is not mandatory but exploits some “optional” features of WS-Addressing.

**Note:**

- This proposal does not require any “persistence” on any intermediary and is fully compliant with WS-Addressing specification.
- The TC asks if, apart from the proposed workaround, there is another standard reference solution for the highlighted problem.

Should there be no other solution apart from the proposed workaround; **the proposal is to extend the WS-Addressing specification in order that the “Message Properties” include a new tag (provisionally named “Final Destination”) to specify the process/transaction result.**

**Moreover the proposal is to make the utilization of this new tag as Mandatory whenever it is necessary to specify a “final destination”, i.e. in presence of a non-direct “requester-consumer” situation.**

Proposed Workaround:

**CASE A:**

1. **C1 invokes WS-A** and specifies in the *replyTo* section of the WS-Addressing header the *EPR (Endpoint Reference)* where it wants to receive the asynchronous response (**C1**).  
(Example: <http://service1.sc.local/response>).
2. The **ESB invokes WSB** and specifies in the *replyTo* section of the WS-Addressing header the *EPR (Endpoint Reference)* where it wants to receive the asynchronous response (Example: <http://service1.esb.local/response>). By doing so it takes the *replyTo* section received by C1 and embeds it in the *referenceParameters* section of *replyTo*. P1 is obliged by WS-Addressing specification to return the *referenceParameters* in the *To* section when sending the asynchronous response.
3. **P1 returns the asynchronous response** to the *replyTo* address (Example: <http://service1.esb.local/response>) specified by the ESB, together with the *referenceParameters* section.
4. The **ESB invokes WSC** and specifies in the *replyTo* section of the WS-Addressing header the *EPR (Endpoint Reference)* where it wants to receive the asynchronous response (Example: <http://service2.esb.local/response>). By doing so it takes the *referenceParameters* section received by WSB and embeds it in the *replyTo* section. P2 is obliged by WS-Addressing specification to return the *referenceParameters* in the *To* section when sending the asynchronous response.

1368

1369 5. **P2 returns the asynchronous response** to the ESB *replyTo* address (Example:  
1370 <http://service2.esb.local/response>) specified by the ESB, which includes the *referenceParameters*  
1371 section.

1372

1373 6. **The ESB gets the *replyTo* info**, embedded in the *referenceParameters* received from P2, to  
1374 address the asynchronous response to **C1**.

1375

1376 **CASE B:**

1377 Same as Case 1 with C2 originator and final destination.
